Commissioner for Patents  
 Washington, D.C. 20231

PRELIMINARY AMENDMENT

Sir:

Prior to examination on the merits, please amend the above-identified application as follows:

IN THE SPECIFICATION:

Please amend the specification by inserting the substitute specification being filed concurrently herewith.

IN THE ABSTRACT:

Please add a new abstract as shown on page 23 of the substitute specification.

IN THE CLAIMS:

Please CANCEL claims 1-25 without prejudice to or disclaimer of the recited subject matter.

Please ADD new claims 26-50 as presented in the substitute specification.

REMARKS

Applicants request favorable consideration and allowance of the subject application in view of the preceding amendments and the following remarks.

Claims 26-50 are presented for consideration, in lieu of claims 1-25, which have been canceled without prejudice or disclaimer. Claims 26 and 40 are independent. Support for these claims can be found in the original application as filed. Therefore, no new matter has been added. Applicants submit that claims 26-50 patentably define features of the method and apparatus for conveying particulate material of the present invention.

Applicants further submit that the instant application is in condition for allowance. Favorable consideration and an early Notice of Allowance are requested.

Applicants' undersigned attorney may be reached in our Washington, D.C. office by telephone at (202) 530-1010. All correspondence should be directed to our address listed below.

Respectfully submitted,

Attorney for Applicants

Steven E. Warner

LETTER FORWARDING SUBSTITUTE SPECIFICATION

Sir:

Applicants submit herewith a substitute specification and request entry thereof in the above-identified application.

For the Examiner's convenience, also provided is a marked-up copy of the original specification showing the portions thereof which are being changed. The substitute specification includes the same changes as are indicated in the marked-up copy.

Applicants' undersigned attorney has reviewed the substitute specification and submits that the substitute specification contains no new matter.

Applicants believe that no fees should be incurred in connection with the filing of this paper. However, the Commissioner is authorized to charge Deposit Account No. 06-1205, should any fees be required. A duplicate of this paper is enclosed for this purpose.

Applicants' undersigned attorney may be reached in our Washington, D.C. office by telephone at (202) 530-1010. All correspondence should be directed to our address listed below.

Respectfully submitted,

Attorney for Applicants  
Steven E. Warner

METHOD AND APPARATUS FOR TREATING HIGH  
PRESSURE PARTICULATE MATERIAL

BACKGROUND OF THE INVENTION

**[0001]** The present invention relates to a method and an apparatus for treating high pressure particulate material.

**[0002]** More particularly, the invention relates to a method and an apparatus for pneumatic conveying of particulate material containing reaction products of a high pressure reactor, by using gas exiting the reactor as a carrier gas, from a supply vessel at a pressure of at least two bar to a receiving vessel at a considerably lower pressure, by using an apparatus comprising a conveyor line and a collecting vessel between the conveyor line and the receiving vessel.

**[0003]** It is generally known to convey solid, powdered or granular material by a pneumatic conveyor system. When transported pneumatically, solid material is conveyed in a tubular conveyor line entrained with the carrier gas flowing therein. Pneumatic conveyance is possible for diluted suspensions, whereby a relatively large quantity of gas conveys a relatively small volume of solid material, or for denser suspensions, whereby a relatively small quantity of gas conveys a relatively large volume of solid material.

**[0004]** Pneumatic conveyance is normally performed by feeding superatmospheric carrier gas to a conveyor line or by providing a low pressure in the receiving vessel in the latter end of the conveyor line. Pneumatic conveyance is especially applicable in situations where the supply vessel is for some other reason at a higher pressure than the receiving vessel. Thus, it could be possible to utilize the gas in the supply vessel for conveying particulate material and it is not necessary to separately arrange a carrier gas supply or pressure difference between the vessels.

**[0005]** U.S. Patent No. 4,699,210 discloses a system to convey fly ash from a pressurized fluidized bed boiler separated by its particle separator in such a way that the material to be conveyed is led from the bottom portion of the separator to an ash container through a conduit in which its flow direction is sharply changed a repeated number of times. Every change of direction consumes energy, however, whereby the pressure of the flue gas conveying the ash is reduced gradually on its way from the particle separator to the ash container.

**[0006]** Another drawback in this conveyor system is clogging of the conveyor line at its sharp bends, especially if the ash temperature decreases close to the dew point temperature of the carrier gas. To prevent clogging of the line, the ash is conveyed as a thin suspension, whereby the flow rate of the gas needs to be high enough, at least 10 - 15 m/s. This results, however, in a high consumption of the carrier gas and thus, increases the energy consumption substantially. In addition, the high flow rate can cause strong erosion, especially at the bends of the line where the flow direction changes.

**[0007]** U.S. Patent No. 4,877,423 discloses a two-stage pneumatic system applicable to conveying and cooling high pressure fly ash, at the first stage of which system, where flue gas is used as a carrier gas, the pressure is reduced only slightly, typically only 0 - 3 bar. In the end section of the first stage is arranged a precipitator to separate flue gas from ash, and a high pressure supply tank for the ash. Subsequent to the supply tank, the system comprises a lock tank separated by a valve, in which tank, the pressure can be reduced to a level required by the further transport and final cooling of the ash.

**[0008]** The disclosed arrangement with a separate precipitator and two tanks is, however, quite complicated and expensive. Furthermore, the ash discharge of the separator, treating the entire ash quantity and having no longer any carrier gas flow, has a tendency to get clogged up, if the ash is adhesive at least to some extent. This also prevents the ash from being efficiently cooled at the first stage.

## SUMMARY OF THE INVENTION

**[0009]** It is an object of the present invention to provide a method and an apparatus for treating particulate material, in which the above-mentioned prior art problems are minimized.

**[0010]** It is a special object of the present invention to provide a simple method and apparatus for controlled pneumatic conveyance and cooling of hot, high pressure particulate material.

**[0011]** It is a further object of the invention to provide a method and an apparatus for pneumatic conveyance of hot, high pressure particulate material, in which no overheating and clogging of the conveyor line occur.

**[0012]** It is also an object of the invention to provide a method and an apparatus, by which the conveying speed of ash can be controlled and the consumption of carrier gas diminished.

**[0013]** In order to solve the above problems, a method according to the present invention is characterized in that a receiving vessel comprises a discharge conduit for carrier gas and means to control the flow rate of the carrier gas, and that the method comprises the steps of:

(a) controlling the pressure in a collecting vessel by using the means to control the flow rate of the carrier gas so that material is conveyed from the supply vessel to the collecting vessel essentially at the same pressure as is prevailing in the supply vessel, and

(b) conveying material from the collecting vessel to the receiving vessel essentially at the same pressure as is prevailing in the receiving vessel.

**[0014]** In order to solve the above prior art problems, an apparatus according to the present invention is characterized in that a receiving vessel comprises a discharge conduit for carrier gas and means to

RECEIVED  
U.S. PATENT OFFICE  
JULY 1973

control the discharge velocity of the carrier gas from the collecting vessel, and means to control the pressure of the particulate material collected in the collecting vessel.

**[0015]** The conveyance according to the present invention includes that the flow rate of gas in the conveyor line is preferably relatively low, most preferably, less than 5 m/s and particulate material is conveyed as a dense suspension. When the present invention is applied, the frictional forces of the conveyor line are relatively small, whereby the relatively small pressure difference compared to the pressure prevailing in the supply vessel, typically less than one bar, between the supply vessel and the collecting vessel, provides a desired flow.

**[0016]** Prior to the conveyance, the particulate material may form a thin or a dense layer, e.g., a fluidized bed, in the bottom of the supply vessel. The conveyor line may be attached to the supply vessel at the bottom or on the side thereof.

**[0017]** Particulate material can be preferably cooled in the conveyor line by arranging the line at least in some portions coaxially so that the particulate material flows in the inner tube and the cooling medium, e.g., water or steam, in the outer tube. A mixer also can be provided between the cooled portions, assuring that the material is cooled uniformly. The cooling may also be performed or intensified by arranging a heat exchange surface in the supply vessel, the collecting vessel or the receiving vessel.

**[0018]** To prevent clod formation in the conveyed material, causing clogging of the conveyor line, the material should not be cooled close to the dew point temperature of the carrier gas, i.e., typically, the flue gas of a reactor. When utilizing the ash conveyance system according to the present invention, the cooling of the material in the conveyor line can be continued to a lower temperature, if air is added to the carrier gas. Preferably, this can be performed by fluidizing the material in the bottom of the supply vessel by air, whereby the flue gas content in the carrier gas is diminished, the

100168804 052205

partial pressure of water, steam and acids is reduced, and the dew point of the carrier gas is decreased.

**[0019]** In the method according to the present invention, the carrier gas flow from the collecting vessel is adjusted so as to create a desired flow rate for the material between the supply vessel and the collecting vessel. As the discharge conduit for the carrier gas is attached to the collecting vessel, the conveyance of the material continues efficiently up to the collecting vessel and the risk that the conveyor line gets clogged up is diminished.

**[0020]** In the following, some preferred embodiments of the present invention are described as applied to the ash conveyance of a pressurized fluidized bed reactor, but equivalent and other embodiments according to the present invention also can be used in connection with other types of reactors and other particulate materials.

**[0021]** If the carrier gas is allowed to discharge from the collecting vessel directly to the open air, a substantial amount of particulate material to be conveyed, e.g., ash, may also be discharged. According to a first preferred embodiment of the invention, the carrier gas is allowed to discharge from the collecting vessel through one or more porous filter elements. The filter elements can be located inside the collecting vessel or in separate gas discharge pipes outside the collecting vessel. From the filter elements, the gas is allowed to be discharged to the open air or to another vessel which is substantially at the same pressure as the receiving vessel, e.g., at atmospheric pressure. The gas flow is controlled by the control elements located downstream of the filter elements, which control elements can comprise, e.g., a control valve or a combination of an orifice plate and a shut-off valve or a combination of a control valve and a shut-off valve.

**[0022]** The ash entrained with the carrier gas to the filter may disturb or even prevent the gas flow. In order to avoid this, the collecting vessel is formed as a settling vessel, whereby it serves as a pre-separator for the ash. As a certain amount of ash is in any case entrained with the carrier gas, the

45018204 062263

filter elements can preferably be cleaned from the material collected on their surfaces by using high pressure gas pulses.

**[0023]** According to a second preferred embodiment of the invention, the carrier gas is allowed to be discharged from the collecting vessel through an orifice having a proper size directly to the receiving vessel. Thus, the ash entrained with the gas is not allowed to reach the environment, but is directed to the receiving vessel. The drawback of this embodiment could be the erosion or plugging of the orifice, deriving from the ash. To eliminate this problem, the orifices are preferably made easily changeable.

**[0024]** To control the ash flow rate, the gas discharge system comprises preferably two or more parallel gas discharge conduits each having an orifice of the same size or of different sizes between the collecting vessel and the receiving vessel. The carrier gas discharge conduits are provided with valves, by shutting and opening of which the gas discharge and the ash flow in the conveyor line can be controlled.

**[0025]** As the gas is discharged to the receiving vessel, the receiving vessel needs to be provided with a gas discharge opening, e.g., open to the open air, and a filter for preventing the ash from exiting through the discharge opening.

**[0026]** The ash conveyor system according to the above preferred first and second embodiments of the present invention is preferably used intermittently, whereby ash is collected in the collecting vessel until its surface reaches a certain predetermined level. After this, the ash collected in the collecting vessel is discharged to the receiving vessel.

**[0027]** As the receiving vessel is typically at atmospheric pressure or at least essentially at a lower pressure than the collecting vessel during the conveyance of the ash, the pressure of the material to be discharged has to be reduced close to the pressure of the receiving vessel before being discharged

from the collecting vessel. To reduce the pressure in the collecting vessel, a shut-off valve can be disposed in the ash conveyor line, preferably, at its end closest to the collecting vessel, making it possible to separate the collecting vessel from the conveyor line.

**[0028]** Preferably, the discharge of the collecting vessel is started by closing the valve controlling the gas exhaust from the collecting vessel. Thus, the gas pressure in the conveyor line is increased essentially to the same pressure level as the gas in the supply vessel, and the ash flow in the conveyor line is stopped. Next, the shut-off valve arranged in the conveyor line is shut and the valve controlling the discharge of the gas in the collecting vessel is reduced. When the pressure is low enough, the collected ash is removed from the collecting vessel to the receiving vessel.

**[0029]** The collecting vessel can preferably be disposed above the receiving vessel, whereby the ash is allowed to fall directly down to the receiving vessel, after the pressure in the collecting vessel has been allowed to fall to the same level as the pressure in the receiving vessel.

**[0030]** The ash also can be conveyed from the collecting vessel to the receiving vessel by other means, e.g., by using a screw or pneumatically, whereby the pressure in the collecting vessel can remain even slightly higher than the pressure in the receiving vessel, when the pressure is reduced, and the carrier gas can be used for conveying the ash to the receiving vessel.

**[0031]** An essential idea of the present invention is that the valve disposed in the conveyor line is not used for controlling the ash conveying speed, but is used only for separating the collecting vessel from the conveyor line after the ash flow has been stopped by the valves controlling the gas discharge.

**[0032]** The valves controlling the gas exhaust can preferably be used not only for stopping the ash conveyance for the discharge of the collecting vessel, but also for controlling the ash conveying speed. It is especially preferable to change the conveying speed intermittently, e.g., so that the

conveyance is performed essentially at constant speed, but is stopped completely at regular intervals. Thus, excessive rising or falling of the temperature as well as the generation of agglomerations disturbing the conveyance can be prevented. If ash is collected only to a minor extent, even carrier gas can be saved by using intermittent ash conveyance, thus improving the efficiency of the plant.

[0033] Intermittent stopping of the ash conveyance can be controlled on the basis of certain variables measured in the conveyance system. The ash conveyance can be stopped, e.g., when the temperature of the ash entering the collecting vessel or the pressure difference between the supply vessel and collecting vessel is too high or too low. Too high a temperature indicates that the volume of ash to be conveyed is so large that the cooling has no time to reduce its temperature sufficiently. Too high a pressure difference indicates that the line might be about to get plugged and the gas discharge from the collecting vessel has to be temporarily shut in order to control the situation.

[0034] On the other hand, too low a pressure difference or temperature of the entering ash can indicate that the ash conveyance is insignificant, probably for the reason that there is no ash in the supply vessel. In this case, the conveyance should be temporarily stopped in order to save carrier gas and energy. Excessive cooling of the ash also increases the risk of plugging the conveyor line. The temperature of the ash entering the collecting vessel is preferably less than 300 °C, and more preferably, 100 - 200 °C. The pressure difference between the supply vessel and the collecting vessel is preferably 0.1 - 1.0 bar or less than 0.3 bar for each ten meters of the conveyor line.

[0035] The conveyor systems according to the above-described first and second embodiments of the present invention can be used, e.g., for conveying fly ash separated by a flue gas filter unit of a pressurized fluidized bed reactor used for combustion or gasification of material.

[0036] According to a third preferred embodiment of the present invention, the collecting vessel has a tubular form and it is arranged in a vertical position so that ash enters the collecting vessel through its upper part. Typically, the proportion of the height and the diameter of the collecting vessel is at

least five, more preferably, at least ten, but it can preferably be even over thirty. Thus, the first gas discharge pipe provided with a filter is preferably disposed in the lower part of the vessel and the ash discharge system in the bottom of the vessel. There are possibly a plurality of gas discharge pipes at various levels of the vessel. The filter attached to the discharge pipes can preferably be arranged inside the tubular collecting vessel in contact with the material to be conveyed.

[0037] When using the ash discharge system according to the third preferred embodiment, the ash disposal from the collecting vessel is preferably controlled by an ash column having an approximately constant height in the tubular collecting vessel. As the carrier gas passes through the ash column, its pressure falls without any separate means, so that ash can be removed from the lower part of the collecting vessel, directly to an ash container, e.g., at atmospheric pressure. This kind of a conveyance system is particularly suitable for removing coarse bottom ash, e.g., from the furnace of a fluidized bed reactor used for combustion or gasification of material.

[0038] The collecting vessel according to the above-described third embodiment can also be dimensioned so that it has a self-adjusting overfill protector. Thus, the diameter and the height of the vessel have to be such that the airflow through the ash columns slows down essentially before the ash column in the vessel is too high, whereby the ash conveyance to the collecting vessel is reduced or even stopped completely.

[0039] In all of the above-described embodiments, the conveyor line comprises parts that can be oriented with any desired position, i.e., vertical, horizontal or oblique. If necessary, the flow of the particulate material in the conveyor line, especially where the line is bent, can be assisted by introducing small quantities of carrier gas, e.g., air, into the line continuously or intermittently.

[0040] The invention is characterized in that there are no valves for controlling the conveying speed of the ash in the ash conveyor line. There can be shut-off valves in the line intended to be used when a portion of the system needs to be separated from the others, e.g., for maintenance.

THE HISTORY OF THE CHURCH OF JESUS CHRIST

## BRIEF DESCRIPTION OF THE DRAWINGS

[0041] In the following, the invention will be described in more detail with reference to the accompanying drawings, in which

[0042] Fig. 1 schematically illustrates an ash conveying system according to a first preferred embodiment of the present invention;

[0043] Fig. 2 schematically illustrates the outlet end of the ash conveying system according to a second preferred embodiment of the present invention; and

[0044] Fig. 3 schematically illustrates the outlet end of the ash conveying system according to a third preferred embodiment of the present invention.

## DESCRIPTION OF THE PREFERRED EMBODIMENTS

[0045] Fig. 1 illustrates an ash conveying system according to a first preferred embodiment of the present invention, in which a supply vessel 10, an ash conveyor line 20 and a receiving vessel 40 can be similar to those even in other preferred embodiments. The various embodiments differ from each other mainly in how the carrier gas discharge from a collecting vessel 30 and the pressure reduction of the collected material are arranged.

[0046] The invention is characterized in that particulate material containing reaction products of a reactor is conveyed pneumatically from a supply vessel 10 at a pressure of at least 2 bar, typically at 6 - 20 bar, to a receiving vessel 40, e.g., at atmospheric pressure, using the gas exiting the reactor as a carrier gas. When applying the invention, the volume of the supply vessel is typically larger than

the volume of the conveyor line and it can be assumed that the pressure of the supply vessel 10 is constant.

**[0047]** The supply vessel 10 can consist, e.g., of a bottom part of a filter for fly ash removal from a high pressure fluidized bed reactor or it can be a part of the removal system for bottom ash from a fluidized bed reactor. In the former case, the ash 12 collected in the supply vessel 10 is powdered, compressible fly ash, whereas in the latter case, the ash could be coarse. The quality of the ash to be conveyed has to be considered when choosing the embodiment and the method, by which the system according to the present invention is applied.

**[0048]** In the supply vessel 10, the ash temperature is typically 400 – 1200 °C and for precooling the ash, the vessel 10 can be provided with heat exchange surfaces 14, e.g., heat exchange pipes, in which water or steam circulates.

**[0049]** The ash is conveyed in a tubular conveyor line 20, in which a heat exchange surface could be arranged, e.g., a sleeve 22 covering the line at least partly and having means 24, 25 for the recirculation of a heat exchange medium, e.g., water or steam. By the heat exchange surfaces 22, the ash temperature can be reduced, e.g., to 150 – 300 °C.

**[0050]** It is possible to arrange means 16 for the introduction of fluidizing gas, e.g., air, at the bottom of the supply vessel 10. This can prevent the clogging of the lower part of the collecting vessel 30 deriving from the arching of the ash. Further, fluidizing air can be mixed in the carrier gas used in the conveyance, to reduce its dew point. Thus, the clogging of the conveyor line due to moistening as the result of the ash cooling can be prevented.

**[0051]** In Fig. 1, the conveyor line 20 starts below the supply vessel 10, turns upwards after the horizontal section and leads again horizontally above the collecting vessel 30. In practice, the conveyor line can consist of parts with any desired position. To avoid the clogging of the line, it

could be occasionally or continuously necessary to add small quantities of carrier gas 28, e.g., air, to some points of the line, especially to the bent sections.

[0052] The ash conveyor line 20 ends in the collecting vessel 30, to which a discharge conduit 50 for carrier gas is attached. The conveyor line 20 is preferably formed of an extension part 32 extending slightly into the collecting vessel and directing the ash towards the bottom of the collecting vessel 30, thus reducing the probability of the ash being entrained with the gas to the discharge conduit 50. The collecting vessel 30 is also formed so as to reduce the speed of the carrier gas essentially when flowing from the extension part 32 of the conveyor line 20 to the collecting vessel. Thus, the collecting vessel serves as a settling chamber for ash, separating a substantial part of the ash conveyed by the carrier gas.

[0053] In the embodiment according to Fig. 1, the discharge conduit 50 is provided with a filter 42 and a control valve 54 for controlling the flow rate of the discharged carrier gas 56. The discharge conduit 50 leads preferably to the open air or to a space essentially at atmospheric pressure. If the pressure of the receiving vessel differs from the atmospheric pressure, it is preferably to draw the discharge conduit 50 to a space essentially at the same pressure as that of the receiving vessel 40.

[0054] As ash can be entrained with the carrier gas to filter 52, the filter 52 is provided with means 60 for cleaning the filter 52 by giving intermittent gas pulses to the clean side thereof.

[0055] In the embodiment according to Fig. 1, the collecting vessel 30 is arranged immediately above the receiving vessel 40. The collecting vessel 30 is separated from the receiving vessel 40 by a gas tight valve 34. There is also a gas tight valve 36 between the collecting vessel 30 and the conveyor line 20.

[0056] The present invention is characterized in that the gas discharge speed is adjusted by a control valve 54 so as to convey ash in the line 20 as a dense suspension, the flow rate of the carrier gas

being less than 5 m/s. Thus, the erosion and consumption of carrier gas caused by the conveyance are relatively insignificant. Valve 34 is shut and valve 36 is open during the conveyance. It is to be noted that valve 36 is not used for controlling the conveying speed of the ash or for stopping thereof.

**[0057]** In the technical solution according to Fig. 1, a valve 18 is also arranged between the supply vessel 10 and the conveyor line 20. The system may include such a valve and possibly even other valves not marked in the figure, as they do not have any significance from the viewpoint of the present invention. Valve 18 could be needed, e.g., when maintaining the system, but in normal operation, the valve is open.

**[0058]** When the level transmitter 38 attached to the collecting vessel 30 indicates that the collecting vessel 30 is about to get filled, the ash conveyance is stopped. The carrier gas flow is stopped by shutting valve 54. When the ash conveyance is stopped, valve 36 is shut. After this, valve 54 is reopened and the pressure of the collecting vessel is allowed to fall so that it is essentially the same as the pressure of the receiving vessel and the ash can fall down into the receiving vessel by opening the valve 34.

**[0059]** To restart the ash conveyance, valve 34 is shut, valve 36 is opened and the ash flow rate is adjusted by valve 54 to a desired value. To protect valve 36, it could be necessary to raise the pressure of the collecting vessel essentially to the same level as that of the supply vessel 10. This can preferably be performed by using a system 50 producing clean pulses for the filter 52 of the discharge conduit 50. Simultaneously, the filter 52 is also cleaned from ash possibly collected on its surface at the preceding filling stage of the collecting vessel 30. The receiving vessel 40 can be provided with heat exchange surfaces 44 for the final cooling of the ash as well as with an opening for ash discharge 46 in the bottom of the vessel 40.

**[0060]** The ash conveyance system according to the present invention is preferably used intermittently also between the discharges of the collecting vessel 30 so that the temperature  $T_1$  of

the ash entering the collecting vessel 30 at the end of the conveyor line 20 and the pressure difference  $\Delta p$  between the supply vessel 10 and the collecting vessel 30 are monitored. When the temperature  $T_1$  or the pressure difference  $\Delta p$  is not within the predetermined limits, the discharge of carrier gas and the ash conveyance are stopped by valve 54. Sometimes, it could be sufficient to perform the ash conveyance in a predetermined way intermittently. The ash conveyance can also be stopped when it is detected that the volume of ash in the supply vessel 10 falls below a predetermined level.

**[0061]** Fig. 2 schematically illustrates the outlet end of the ash conveying system according to a second preferred embodiment of the present invention. There, the collecting vessel 130, receiving vessel 140, valves 136 and 134 and the parts not shown in the figure are similar to those in the embodiment according to Fig. 1. The operation principle of this embodiment is also similar to that of the embodiment according to Fig. 1.

**[0062]** The second preferred embodiment according to Fig. 2 differs from the first preferred embodiment according to Fig. 1 in that the discharge conduit for carrier gas is in communication with the receiving vessel 140. Thus, the ash entrained with the carrier gas is also led to the receiving vessel 140. Naturally, when using the second preferred embodiment according to Fig. 2, the receiving vessel 140 has to be provided with a discharge conduit 162 for gas, e.g., to open the open air, and a filter 162 preventing the ash from being entrained out with the gas.

**[0063]** In the embodiment according to Fig. 2, the discharge conduit is divided into three parallel conduits 150, 150', 150" joining to one conduit 160 before reaching the receiving vessel 140. As the ash entrained with the carrier gas could deteriorate the operational condition of the control valve, the control valve 54 of Fig. 1 has been replaced by steadier shut-off valves 154, 154', 154" and critical openings 158, 158', 158", like or unlike each other, restricting the gas flow. Naturally, the number of parallel conduits can also be different from three.

**[0064]** In the embodiment according to Fig. 2, the ash conveying speed can be controlled by opening a necessary number of the shut-off valves 154, 154', 154''. If ash is conveyed periodically, the extent of the conveyance can also be regulated by changing the duration of the periods, whereby it is not necessary to have more than one discharge conduit, shut-off valve and critical opening.

**[0065]** Fig. 3 schematically illustrates the outlet end of the ash conveying system according to a third preferred embodiment of the present invention. In this embodiment, the collecting vessel 230 at the end of the conveyor line is narrow and high, even though its diameter is larger than that of the conveyor line. The proportion of the height of the collecting vessel to its diameter is preferably at least five, most preferably at least ten.

**[0066]** When conveying ash, an ash column is maintained in the collecting vessel 230 extending preferably at least to the center part of the vessel 230. In the embodiment according to the figure, the ash flow is regulated by a discharge conduit 250 for carrier gas attached to the center part of the collecting vessel 230, in which conduit, the volume of carrier gas 256 can be regulated by a valve 254. At the end of the discharge conduit 250 closest to the collecting vessel 230 is arranged a filter 252 preventing the ash from entering the discharge conduit 250. When the filter 252 is disposed according to the figure inside the ash column flowing downwards, the moving ash simultaneously cleans the outer surface of the filter 252 and prevents the filter 252 from being clogged up.

**[0067]** Another advantage gained by arranging the first end of the discharge conduit 250 in the area of the ash column is that the portion of the ash column above the joining point of the discharge conduit 250 also acts as a restrictor for the carrier gas flow. Thus, the ash conveyance is partly self-adjusting as the high ash column slows down the gas flow and reduces or even stops the ash conveyance, when the collecting vessel 230 is about to get filled.

**[0068]** The discharge conduit 250 can also be arranged in the upper part of the collecting vessel 230, whereby it functions in the same way as the discharge conduit 50 according to the first preferred

embodiment in Fig. 1. It is also possible to connect the discharge conduit 250 to the lower part of the collecting vessel 230, whereby the flow regulating effect of the ash column is at its highest.

**[0069]** Fig. 3 also shows another discharge conduit 260 for gas provided with a filter 262 and a control valve 264. The purpose of the discharge conduit 260 is to let the carrier gas 266, discharged from the lower part of the collecting vessel 230, enter the open air without any particular obstruction, i.e., during the ash conveyance, valve 264 does not essentially limit the gas flow. Thus, the lower part of the collecting vessel 230 reaches the atmospheric pressure and the ash 272 can be easily removed from the lower part of the collecting vessel 230 to the receiving vessel (not shown), e.g., by using a rotary feeder 270. The discharge apparatus for ash at the bottom of the collecting vessel 230 can also be of another type, e.g., a conveyor screw or an L-valve. Pressure adjusting in the collecting vessel 230 can also be practiced in many steps, whereby more than the mentioned two discharge conduits 250 for gas are disposed in the collecting vessel 230.

**[0070]** Fig. 3 also shows a level transmitter 238 provided in the upper part of the collecting vessel 230, and an apparatus 258 for feeding high pressure cleaning pulses to the filters 252 and 262. The collecting vessel 230 can also be used so that the upper surface of the ash column is continuously maintained at a desired predetermined level by using a rotary feeder 270. Another possibility is to use a rotary feeder intermittently, whereby the ash level remains within certain predetermined limits.

**[0071]** When starting the ash treatment system according to Fig. 3, e.g., sand can be fed to the collecting vessel 230 through a separate conduit not shown in Fig. 3, whereby a sand column restricts the gas flow at the starting stage.

**[0072]** The invention has just been described in connection with embodiments that are presently considered to be the most preferable. It must, however, be understood that the invention is not limited to these embodiments. Rather, it covers a number of other arrangements within the scope of

invention determined by the claims below. For example, a plurality of ash conveyor lines can lead into the same collecting vessel.

WE CLAIM:

26. A method of conveying particulate material containing reaction products of a high pressure reactor, from a supply vessel at a pressure of at least two bar to a receiving vessel at a considerably lower pressure, by using an apparatus including a conveyor line attached to the supply vessel and a collecting vessel between the conveyor line and the receiving vessel, wherein the collecting vessel includes a discharge conduit for the carrier gas and means to control the discharge rate of the carrier gas, said method comprising the steps of:

- (a) conveying particulate material from the supply vessel to the collecting vessel pneumatically by using the gas exiting the reactor as a carrier gas, controlling the discharge rate of the carrier gas to control the pressure in the collecting vessel and the flow rate of the particulate material in the conveyor line, and conveying material from the supply vessel to the collecting vessel essentially at the same pressure as is prevailing in the supply vessel;
- (b) reducing pressure of the material collected in the collecting vessel; and
- (c) conveying material from the collecting vessel directly to the receiving vessel essentially at the same pressure as is prevailing in the receiving vessel.

27. A method according to claim 26, further comprising performing step (a) by conveying particulate material as a dense suspension, the flow rate of the carrier gas in the conveyor line being less than 5 m/s and the pressure drop being 0.1 - 1.0 bar.

28. A method according to claim 26, wherein the temperature of the particulate material in the supply vessel is 400 - 1200 °C and further comprising providing the conveyor line with heat exchange surfaces, by which the temperature of the particulate material in step (a) is reduced to less than 300 °C.

DRAFT - 4.0 - 2023

29. A method according to claim 28, further comprising fluidizing the particulate material in the supply vessel by air that is mixed in the carrier gas, thus decreasing the dew point of the carrier gas.

30. A method according to claim 26, further comprising arranging a filter in the discharge conduit for the carrier gas, wherein the means to control the flow rate of the gas includes a control valve downstream from the filter, and discharging in step (a) the carrier gas from the collecting vessel to a space at a pressure which is essentially the same as is prevailing in the receiving vessel.

31. A method according to claim 26, further comprising discharging the carrier gas from the collecting vessel to the receiving vessel in step (a).

32. A method according to claim 31, further comprising providing more than one parallel line for the discharge of the carrier gas between the collecting vessel and the receiving vessel, which lines are provided with a constantly open flow restricting element and a shut-off valve, and performing the control of the discharge velocity by opening and shutting the shut-off valves.

33. A method according to claim 32, wherein the flow restricting elements are easily changeable.

34. A method according to claim 30, wherein the collecting vessel has an elongated form and is arranged in a vertical orientation, and further comprising maintaining a column of particulate material in the collecting vessel, and attaching the discharge conduit for carrier gas to the collecting vessel at the bottom section of the particulate material column.

35. A method according to claim 34, further comprising providing more than one discharge conduit for the carrier gas, the discharge conduits being attached to the collecting vessel at various levels of the particulate material column.

100-148354-000200-00

36. A method according to claim 34, further comprising maintaining the pressure in the bottom section of the particulate material column to be approximately the same as is prevailing in the receiving vessel and practicing step (c) intermittently or continuously from the bottom section of the collecting vessel.

37. A method of conveying particulate material according to claim 26, further comprising disposing a gas tight inlet valve in the conveyor line before the collecting vessel and a gas tight discharge valve between the collecting vessel and the receiving vessel, and practicing steps (a) - (c) in alteration, wherein steps (b) and (c) further comprise the sub-steps of:

(b1) stopping the discharge of the carrier gas from the collecting vessel by using the means to control the carrier gas flow, whereby the conveyance of particulate material is stopped;

(b2) closing the shut-off valve before the collecting vessel;

(b3) allowing the discharge of the carrier gas from the collecting vessel until the pressure in the collecting vessel has dropped approximately to the same level as the pressure of the receiving vessel;

(c1) opening the discharge valve and conveying the particulate material from the collecting vessel to the receiving vessel; and

(c2) closing the discharge valve, opening the inlet valve and returning to step (a).

38. A method according to claim 26, further comprising disposing the collecting vessel above the receiving vessel and, in step (c), allowing the particulate material to fall down to the receiving vessel.

40010334.00000000

39. A method according to claim 26, further comprising in step (a), periodically changing the flow rate of the carrier gas by stopping the conveyance for a predetermined period of time at regular intervals or when the pressure in the collecting vessel or the temperature of the material entering the collecting vessel is not within predetermined limits.

40. An apparatus for pneumatically conveying particulate material containing reaction products of a high pressure reactor from a supply vessel at a pressure of at least two bar to a receiving vessel at a considerably lower pressure, said apparatus comprising:

    a conveyor line attached to the supply vessel;  
    a collecting vessel between the conveyor line and the receiving vessel, said collecting vessel comprising (i) a discharge conduit for the carrier gas, (ii) means to control the discharge velocity of the carrier gas from the collecting vessel, and (iii) means to control the pressure of the material collected in the collecting vessel; and

    means for conveying the material directly from the collecting vessel to the receiving vessel essentially at the same pressure as is prevailing in the receiving vessel.

41. An apparatus according to claim 40, further comprising heat exchange surfaces disposed in the conveyor line.

42. An apparatus according to claim 41, further comprising disposing elements for fluidizing the particulate material in the supply vessel in such a way that air used for the fluidization is mixed in the carrier gas, thus decreasing the dew point of the carrier gas.

43. An apparatus according to claim 40, further comprising a filter disposed in the discharge conduit for the carrier gas, wherein the means to control the flow rate of the carrier gas includes a control valve arranged downstream from the filter, and the discharge conduit for the carrier gas is in flow communication with the open air.

201835105205

10018804-062202

44. An apparatus according to claim 40, wherein the discharge conduit for the carrier gas is in flow communication with the receiving vessel.

45. An apparatus according to claim 44, further comprising more than one parallel line for the discharge of the carrier gas provided between the collecting vessel and the receiving vessel, which lines are provided with a constantly open flow restricting element and a shut-off valve.

46. An apparatus according to claim 45, wherein the flow restricting elements are easily changeable.

47. An apparatus according to claim 40, wherein the collecting vessel has an elongated form and is disposed in a vertical orientation, and the discharge conduit for the carrier gas is attached to a bottom section of the collecting vessel.

48. An apparatus according to claim 47, further comprising more than one discharge conduit for the carrier gas, which are attached to the collecting vessel at various levels.

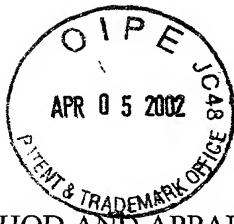

49. An apparatus according to claim 40, further comprising a gas tight valve disposed in the conveyor line before the collecting vessel and between the collecting vessel and the receiving vessel.

50. An apparatus according to claim 40, wherein the collecting vessel is disposed above the receiving vessel and further comprising a valve arranged between the vessels, through which valve the particulate material may fall down to the receiving vessel.

## ABSTRACT

An apparatus for pneumatically conveying particulate material containing reaction products of a high pressure reactor from a supply vessel at a pressure of at least two bar to a receiving vessel at a considerably lower pressure. The apparatus includes a conveyor line attached to the supply vessel, a collecting vessel between the conveyor line and the receiving vessel, the collecting vessel including (i) a discharge conduit for the carrier gas, (ii) a device for controlling the discharge velocity of the carrier gas from the collecting vessel, and (iii) a device for controlling the pressure of the material collected in the collecting vessel, and a device for conveying the material directly from the collecting vessel to the receiving vessel essentially at the same pressure as is prevailing in the receiving vessel.

82922\_1

METHOD AND APPARATUS FOR TREATING HIGH  
PRESSURE PARTICULATE MATERIAL

## BACKGROUND OF THE INVENTION

[0001] The present invention relates to a method and an apparatus for treating high pressure particulate material [as defined in the preambles of the independent claims].

[0002] [Thus] More particularly, the invention relates to a method and an apparatus for pneumatic conveying of particulate material containing reaction products of a high pressure reactor, by using [the] gas exiting the reactor as a carrier gas, from a supply vessel at a pressure of at least [2] two bar to a receiving vessel at a considerably lower pressure, by using an apparatus comprising a conveyor line and a collecting vessel between the conveyor line and the receiving vessel.

[0003] It is generally known to convey solid, powdered or granular material by a pneumatic conveyor system. When transported pneumatically, solid material is conveyed in a tubular conveyor line entrained with the carrier gas flowing therein. Pneumatic conveyance is possible for diluted suspensions, whereby a relatively large quantity of gas conveys a relatively small volume of solid material, or for denser suspensions, whereby a relatively small quantity of gas conveys a relatively large volume of solid material.

[10004] Pneumatic conveyance is normally performed by feeding superatmospheric carrier gas to a conveyor line or by providing a low pressure in the receiving vessel in the latter end of the conveyor line. Pneumatic conveyance is especially applicable in situations where the supply vessel is for some other reason at a higher pressure than the receiving vessel. Thus, it could be

possible to utilize the gas in the supply vessel for conveying particulate material and it is not necessary to separately arrange a carrier gas supply or pressure difference between the vessels.

[0005] [US patent] U.S. Patent No. 4,699,210 discloses a system to convey fly ash from a pressurized fluidized bed boiler separated by its particle separator in such a way that the material to be conveyed is led from the bottom portion of the separator to [the] an ash container through a conduit [where] in which its flow direction is sharply changed [repeated] a repeated number of times. Every change of direction consumes energy, however, whereby the pressure of the flue gas conveying the ash is reduced gradually on its way from the particle separator to the ash container.

[0006] [A] Another drawback in this conveyor system is [the] clogging of the conveyor [line's] line at its sharp bends, especially if the ash temperature decreases close to the dew point temperature of the carrier gas. To prevent [the] clogging of the line, the ash is conveyed as a thin suspension, whereby the flow rate of the gas needs to be high enough, at least 10 - 15 m/s. This results, however, in a high consumption of the carrier gas and thus, increases [thus] the energy consumption substantially. In addition, the high flow rate can cause strong erosion, especially at the bends of the line where the flow direction changes.

[0007] [US patent] U.S. Patent No. 4,877,423 discloses a two-stage pneumatic system applicable to conveying and cooling high pressure fly ash, at the first stage of which system, where flue gas is used as a carrier gas, the pressure is reduced only slightly, typically only 0 - 3 bar. In the end section of the first stage is arranged a precipitator to separate flue gas from ash, and a high pressure supply tank for the ash. Subsequent to the supply tank, the system comprises a lock tank separated by a valve, in which tank, the pressure can be reduced to a level required by the further transport and final cooling of the ash.

**[0008]** The disclosed arrangement with a separate precipitator and two tanks is, however, quite complicated and expensive. Furthermore, the ash discharge of the separator, treating the entire ash quantity and having no longer any carrier gas flow, has a tendency to get clogged up, if the ash is adhesive at least to some extent. This also prevents the ash from being efficiently cooled at the first stage.

#### SUMMARY OF THE INVENTION

**[0009]** It is an object of the present invention to provide a method and an apparatus for treating particulate material, in which the above-mentioned prior art problems are minimized.

**[0010]** It is a special object of the present invention to provide a simple method and apparatus for controlled pneumatic conveyance and cooling of hot, high pressure particulate material.

**[0011]** It is a further object of the invention to provide a method and an apparatus for pneumatic conveyance of hot, high pressure particulate material, in which no overheating and clogging of the conveyor line occur.

**[0012]** It is also an object of the invention to provide a method and an apparatus, by which the conveying speed of ash can be controlled and the consumption of carrier gas diminished.

**[0013]** In order to solve the above problems, a method[, the characterizing features of which are disclosed in the characterizing part of the independent method claim, is provided. Thus the method] according to the present invention is characterized in that [the] a receiving vessel comprises a discharge conduit for carrier gas and means to control the flow rate of the carrier gas, and that the method comprises the steps of:

20250716PCT00001

- (a) controlling the pressure in [the] a collecting vessel by using the means to control the flow rate of the carrier gas so that material is conveyed from the supply vessel to the collecting vessel essentially at the same pressure as is prevailing in the supply vessel, and
- (b) conveying material from the collecting vessel to the receiving vessel essentially at the same pressure as is prevailing in the receiving vessel.

[0014] In order to solve the above prior art problems, an apparatus[ , the characterizing features of which are disclosed in the characterizing part of the independent apparatus claim, is also provided. Thus the apparatus] according to the present invention is characterized in that [the] a receiving vessel comprises a discharge conduit for carrier gas and means to control the discharge velocity of the carrier gas [form] from the collecting vessel, and means to control the pressure of the particulate material collected in the collecting vessel.

[0015] The conveyance according to the present invention includes that the flow rate of gas in the conveyor line is preferably relatively low, most preferably, less than 5 m/s and particulate material is conveyed as a dense suspension. When the present invention is applied, the frictional forces of the conveyor line are relatively small, whereby the relatively small pressure difference compared to the pressure prevailing in the supply vessel, typically less than [1] one bar, between the supply vessel and the collecting vessel, provides a desired flow.

[0016] Prior to the conveyance, the particulate material may form a thin or a dense layer, e.g., a fluidized bed, in the bottom of the supply vessel. The conveyor line may be attached to the supply vessel at the bottom or on the side thereof.

[0017] Particulate material can be preferably cooled in the conveyor line by arranging the line at least in some [part/-s] portions coaxially so that the particulate material flows in the inner tube and the cooling medium, e.g., water or steam, in the outer tube. A mixer also can be [also] provided between the cooled [parts securing] portions, assuring that the material is cooled

uniformly. The cooling may also be performed or intensified by arranging a heat exchange surface in the supply vessel, the collecting vessel or [in] the receiving vessel.

**[0018]** To prevent clod formation in the conveyed material, causing clogging of the conveyor line, the material should not be cooled close to the dew point temperature of the carrier gas, i.e., typically, the flue gas of a reactor. When utilizing the ash conveyance system according to the present invention, the cooling of the material in the conveyor line can be continued to a lower temperature, if air is added to the carrier gas. Preferably, this can be performed by fluidizing the material in the bottom of the supply vessel by air, whereby the flue gas content in the carrier gas is diminished, the partial pressure of water, steam and acids is reduced, and the dew point of the carrier gas is decreased.

**[0019]** In the method according to the present invention, the carrier gas flow from the collecting vessel is adjusted so as to create a desired flow rate for the material between the supply vessel and the collecting vessel. As the discharge conduit for the carrier gas is attached to the collecting vessel, the conveyance of the material continues efficiently up to the collecting vessel and the risk that the conveyor line gets clogged up is diminished.

**[0020]** In the following, some preferred embodiments of the present invention are described as applied to the ash conveyance of a pressurized fluidized bed reactor, but equivalent and other embodiments according to the present invention also can be used [also] in connection with other types of reactors and other particulate materials.

**[0021]** If the carrier gas is allowed to discharge from the collecting vessel directly to the open air, a substantial amount of particulate material to be conveyed, e.g., ash, may also be discharged. According to a first preferred embodiment of the invention, the carrier gas is allowed to discharge from the collecting vessel through one or more porous filter [element/-s] elements. The filter elements can be located inside the collecting vessel or in separate gas discharge pipes

100-168-604-055202

outside the collecting vessel. From the filter elements, the gas is allowed to [discharge] be discharged to the open air or to another vessel which is substantially at the same pressure as the receiving vessel, e.g., at atmospheric pressure. The gas flow is controlled by the control elements located downstream of the filter elements, which control elements can comprise, e.g., a control valve or a combination of an orifice plate and a shut-off valve or a combination of a control valve and a shut-off valve.

**[0022]** The ash entrained with the carrier gas to the filter may disturb or even prevent the gas flow. In order to avoid this, the collecting vessel is formed as a settling vessel, whereby it serves as a preseparator for the ash. As a certain amount of ash is in any case entrained with the carrier gas, the filter elements can preferably be cleaned from the material collected on their surface surfaces by using high pressure gas pulses.

**[0023]** According to a second preferred embodiment of the invention, the carrier gas is allowed to [discharge] be discharged from the collecting vessel through an orifice [of] having a proper size directly to the receiving vessel. Thus, the ash entrained with the gas is not allowed to reach the environment, but is directed to the receiving vessel. The drawback of this embodiment could be the erosion or plugging of the orifice, deriving from the ash. To eliminate this problem, the orifices are preferably made easily changeable.

**[0024]** To control the ash flow rate, the gas discharge system comprises preferably two or more parallel gas discharge conduits each having an orifice of the same size or of different sizes between the collecting vessel and the receiving vessel. The carrier gas discharge conduits are provided with valves, by shutting and opening of which the gas discharge and the ash flow in the conveyor line can be controlled.

**[0025]** As the gas is discharged to the receiving vessel, the receiving vessel needs to be provided with a gas discharge opening, e.g., open to the open air, and a filter for preventing the ash from exiting through the discharge opening.

**[0026]** The ash conveyor system according to the above preferred first and second embodiments of the present invention is preferably used intermittently, whereby ash is collected in the collecting vessel until its surface reaches a certain predetermined level. After this, the ash collected in the collecting vessel is discharged to the receiving vessel.

**[0027]** As the receiving vessel is typically at atmospheric pressure or at least essentially at a lower pressure than the collecting vessel during the conveyance of the ash, the pressure of the material to be discharged has to be reduced close to the pressure of the receiving vessel before [discharging] being discharged from the collecting vessel. To reduce the pressure in the collecting vessel, a shut-off valve can be disposed in the ash conveyor line, preferably, at its end closest to the collecting vessel, making it possible to separate the collecting vessel from the conveyor line.

**[0028]** Preferably, the discharge of the collecting vessel is started by closing the valve controlling the gas exhaust from the collecting vessel. Thus, the gas pressure in the conveyor line is increased essentially to the same pressure level as the gas in the supply vessel, and the ash flow in the conveyor line is stopped. Next, the shut-off valve arranged in the conveyor line is shut and the valve controlling the discharge of the gas in the collecting vessel is reduced. When the pressure is low enough, the collected ash is removed from the collecting vessel to the receiving vessel.

**[0029]** The collecting vessel can preferably be disposed above the receiving vessel, whereby the ash is allowed to fall directly down to the receiving vessel, after the pressure in the collecting vessel has been allowed to fall to the same level as the pressure in the receiving vessel.

[0030] The ash also can be conveyed from the collecting vessel to the receiving vessel [also] by other means, e.g., by using a screw or pneumatically, whereby the pressure in the collecting vessel can remain even slightly higher than the pressure in the receiving vessel, when the pressure is reduced, and the carrier gas can be used for conveying the ash to the receiving vessel.

[0031] [The] An essential idea of the present invention is that the valve disposed in the conveyor line is not used for controlling the ash conveying speed, but is used only for separating the collecting vessel from the conveyor line after the ash flow has been stopped by the valves controlling the gas discharge.

[0032] The valves controlling the gas exhaust can preferably be used not only for stopping the ash conveyance for the discharge of the collecting vessel, but also for controlling the ash conveying speed. It is especially preferable to change the conveying speed intermittently, e.g., so that the conveyance is performed essentially at constant speed, but is stopped completely at regular intervals. Thus, excessive rising or falling of the temperature as well as the generation of agglomerations disturbing the conveyance can be prevented. If ash is collected only to a minor extent, even carrier gas can be saved by using intermittent ash conveyance, thus improving the efficiency of the plant.

[0033] Intermittent stopping of the ash conveyance can be controlled on the basis of certain variables measured in the conveyance system. The ash conveyance can be stopped, e.g., when the temperature of the ash entering the collecting vessel or the pressure difference between the supply vessel and collecting vessel is too high or too low. Too high a temperature indicates that the volume of ash to be conveyed is so large that the cooling has no time to reduce its temperature sufficiently. Too high a pressure difference indicates that the line might be about to get plugged and the gas discharge from the collecting vessel has to be temporarily shut in order to control the situation.

10046604.063362

[0034] On the other hand, too low a pressure difference or temperature of the entering ash can indicate that the ash conveyance is insignificant, probably for the reason that there is no ash in the supply vessel. In this case, the conveyance should be temporarily stopped in order to save carrier gas and energy. Excessive cooling of the ash also increases the risk of plugging the conveyor line. The temperature of the ash entering the collecting vessel is preferably less than 300 °C, and more preferably, 100 - 200 °C. The pressure difference between the supply vessel and the collecting vessel is preferably 0.1 - 1.0 bar or less than 0.3 bar for each [10 m] ten meters of the conveyor line.

[0035] The conveyor systems according to the above-described first and second embodiments of the present invention can be used, e.g., for conveying fly ash separated by a flue gas filter unit of a pressurized fluidized bed reactor used for combustion or gasification of material.

[0036] According to a third preferred embodiment of the present invention, the collecting vessel has a tubular form and it is arranged in a vertical position so that ash enters the collecting vessel through its upper part. Typically, the proportion of the height and the diameter of the collecting vessel is at least [5] five, more preferably, at least [10] ten, but it can preferably be even over [30] thirty. Thus, the first gas discharge pipe provided with a filter is preferably disposed in the lower part of the vessel and the ash discharge system in the bottom of the vessel. There are possibly a plurality of gas discharge pipes at various levels of the vessel. The filter attached to the discharge pipes can preferably be arranged inside the tubular collecting vessel in contact with the material to be conveyed.

[0037] When using the ash discharge system according to the third preferred embodiment, the ash disposal from the collecting vessel is preferably controlled by an ash column having an approximately constant height in the tubular collecting vessel. As the carrier gas passes through the ash column, its pressure falls without any separate means, so that ash can be removed from

the lower part of the collecting vessel, directly to an ash container, e.g., at atmospheric pressure. This kind of a conveyance system is particularly suitable for removing coarse bottom ash, e.g., from the furnace of a fluidized bed reactor used for combustion or gasification of material.

**[0038]** The collecting vessel according to the above-described third embodiment can also be dimensioned so that it has a self-adjusting overfill protector. Thus, the diameter and the height of the vessel have to be such that the airflow through the ash columns slows down essentially before the ash column in the vessel is too high, whereby the ash conveyance to the collecting vessel is reduced or even stopped completely.

**[0039]** In all of the above-described embodiments, the conveyor line comprises parts that can be oriented with any desired position, i.e., vertical, horizontal or oblique. If necessary, the flow of the particulate material in the conveyor line, especially where the line is bent, can be assisted by introducing small quantities of carrier gas, e.g., air, into the line continuously or intermittently.

**[0040]** The invention is characterized in that there are no valves for controlling the conveying speed of the ash in the ash conveyor line. There can be shut-off valves in the line intended to be used when a part portion of the system needs to be separated from the others, e.g., for maintenance.

#### BRIEF DESCRIPTION OF THE DRAWINGS

**[0041]** In the following, the invention will be described [more closely] in more detail with reference to the accompanying drawings, in which

**[0042]** ¶Fig. 1 schematically illustrates an ash conveying system according to a first preferred embodiment of the present invention;

400168864-062665

[0043] Fig. 2 schematically illustrates the outlet end of the ash conveying system according to a second preferred embodiment of the present invention; and

[0044] Fig. 3 schematically illustrates the outlet end of the ash conveying system according to a third preferred embodiment of the present invention[;].

#### DESCRIPTION OF THE PREFERRED EMBODIMENTS

[0045] Fig. 1 illustrates an ash conveying system according to a first preferred embodiment of the present invention, [the] in which a supply vessel 10, an ash conveyor line 20 and a receiving vessel 40 [of which] can be similar to those even in other preferred embodiments. The various embodiments differ from each other mainly in how the carrier gas discharge from [the] a collecting vessel 30 and the pressure reduction of the collected material are arranged.

[0046] The invention is characterized in that particulate material containing reaction products of a reactor is conveyed pneumatically from a supply vessel 10 at a pressure of at least 2 bar, typically at 6 - 20 bar, to a receiving vessel 40, e.g., at atmospheric pressure, using the gas exiting the reactor as a carrier gas. When applying the invention, the volume of the supply vessel is typically larger than the volume of the conveyor line and it can be assumed that the pressure of the supply vessel 10 is constant.

[0047] The supply vessel 10 can consist, e.g., of a bottom part of a filter for fly ash removal from a high pressure fluidized bed reactor or it can be a part of the removal system for bottom ash from a fluidized bed reactor. In the former case, the ash 12 collected in the supply vessel 10 is powdered, compressible fly ash, whereas in the latter case, the ash could be coarse. The quality of the ash to be conveyed has to be considered when choosing the embodiment and the method, by which the system according to the present invention is applied.

100143854052206

[0048] In the supply vessel 10, the ash temperature is typically 400 – 1200 °C and for precooling the ash, the vessel 10 can be provided with heat exchange surfaces 14, e.g., heat exchange pipes, in which water or steam circulates.

[0049] The ash is conveyed in a tubular conveyor line 20, in which a heat exchange surface could be arranged, e.g., a sleeve 22 covering the line at least partly and having means 24, 25 for the recirculation of a heat exchange medium, e.g., water or steam. By the heat exchange surfaces 22, the ash temperature can be reduced, e.g., to 150 – 300 °C.

[0050] It is possible to arrange means 16 for the introduction of fluidizing gas, e.g., air, at the bottom of the supply vessel 10. [These] This can prevent the clogging of the lower part of the collecting vessel 30 deriving from the arching of the ash. Further, fluidizing air can be mixed in the carrier gas used in the conveyance, [and] to reduce its dew point. Thus, the clogging of the conveyor line due to moistening as the result of the ash cooling can be prevented.

[0051] In Fig. 1, the conveyor line 20 starts below the supply vessel 10, turns upwards after the horizontal section and leads again horizontally above the collecting vessel 30. In practice, the conveyor line can consist of parts with any desired position. To avoid the clogging of the line, it could be occasionally or continuously necessary to add small quantities of carrier gas 28, e.g., air, to some points of the line, especially to the bent sections.

[0052] The ash conveyor line 20 ends in the collecting vessel 30, to which a discharge conduit 50 for carrier gas is attached. The conveyor line 20 is preferably formed of an extension part 32 extending slightly into the collecting vessel and directing the ash towards the bottom of the collecting vessel 30, thus reducing the probability of the ash being entrained with the gas to the discharge conduit 50. The collecting vessel 30 is also formed so as to reduce the speed of the carrier gas essentially when flowing from the extension part 32 of the conveyor line 20 to the

collecting vessel. Thus, the collecting vessel serves as a settling chamber for ash, separating a substantial part of the ash conveyed by the carrier gas.

**[0053]** In the embodiment according to Fig. 1, the discharge conduit 50 is provided with a filter 42 and a control valve 54 for controlling the flow rate of the discharged carrier gas 56. The discharge conduit 50 leads preferably to the open air or to a space essentially at atmospheric pressure. If the pressure of the receiving vessel differs from the atmospheric pressure, it is preferably to draw the discharge conduit 50 to a space essentially at the same pressure as that of the receiving vessel 40.

**[0054]** As ash can be entrained with the carrier gas to filter 52, the filter 52 is provided with means 60 for cleaning the filter 52 by giving intermittent gas pulses to the clean side thereof.

**[0055]** In the embodiment according to Fig. 1, the collecting vessel 30 is arranged immediately above the receiving vessel 40. The collecting vessel 30 is separated from the receiving vessel 40 by a gas tight valve 34. There is also a gas tight valve 36 between the collecting vessel 30 and the conveyor line 20.

**[0056]** The present invention is characterized in that the gas discharge speed is adjusted by a control valve 54 so as to convey ash in the line 20 as a dense suspension, the flow rate of the carrier gas being less than 5 m/s. Thus, the erosion and consumption of carrier gas caused by the conveyance are relatively insignificant. Valve 34 is shut and valve 36 is open during the conveyance. It is to be noted that valve 36 is not used for controlling the conveying speed of the ash or for stopping thereof.

**[0057]** In the technical solution according to Fig. 1, a valve 18 is also arranged between the supply vessel 10 and the conveyor line 20. The system may include such a valve and possibly even other valves not marked in the figure, as they do not have any significance from the

viewpoint of the present invention. Valve 18 could be needed, e.g., when maintaining the system, but in normal operation, the valve is open.

[0058] When the level transmitter 38 attached to the collecting vessel 30 indicates that the collecting vessel 30 is about to get filled, the ash conveyance is stopped. The carrier gas flow is stopped by shutting valve 54. When the ash conveyance is stopped, valve 36 is shut. After this, valve 54 is reopened and the pressure of the collecting vessel is allowed to fall so that it is essentially the same as the pressure of the receiving vessel and the ash can fall down into the receiving vessel by opening the valve 34.

[0059] To restart the ash conveyance, valve 34 is shut, valve 36 is opened and the ash flow rate is adjusted by valve 54 to a desired value. To protect valve 36, it could be necessary to raise the pressure of the collecting vessel essentially to the same level as that of the supply vessel 10. This can preferably be performed by using a system 50 producing clean pulses for the filter 52 of the discharge conduit 50. Simultaneously, the filter 52 is also cleaned from ash possibly collected on its surface at the preceding filling stage of the collecting vessel 30. The receiving vessel 40 can be provided with heat exchange surfaces 44 for the final cooling of the ash as well as with an opening for ash discharge 46 in the bottom of the vessel 40.

[0060] The ash conveyance system according to the present invention is preferably used intermittently also between the discharges of the collecting vessel 30 so that the temperature  $T_1$  of the ash entering the collecting vessel 30 at the end of the conveyor line 20 and the pressure difference  $\Delta p$  between the supply vessel 10 and the collecting vessel 30 are monitored. When the temperature  $T_1$  or the pressure difference  $\Delta p$  is not within the predetermined limits, the discharge of carrier gas and the ash conveyance are stopped by valve 54. Sometimes, it could be sufficient to perform the ash conveyance in a predetermined way intermittently. The ash conveyance can also be stopped when it is detected that the volume of ash in the supply vessel 10 falls below a predetermined level.

[0061] Fig. 2 schematically illustrates the outlet end of the ash conveying system according to a second preferred embodiment of the present invention. There, the collecting vessel 130, receiving vessel 140, valves 136 and 134 and the parts [missing] not shown in the figure are similar to those in the embodiment according to Fig. 1. The operation principle of this embodiment is also similar to that of the embodiment according to Fig. 1.

[0062] The second preferred embodiment according to Fig. 2 differs from the first preferred embodiment according to Fig. 1 in that the discharge conduit for carrier gas is in communication with the receiving vessel 140. Thus, [also] the ash entrained with the carrier gas is also led to the receiving vessel 140. Naturally, when using the second preferred embodiment according to Fig. 2, the receiving vessel 140 has to be provided with a discharge conduit 162 for gas, e.g., to open the open air, and a filter 162 preventing the ash from being entrained out with the gas.

[0063] In the embodiment according to Fig. 2, the discharge conduit is divided into three parallel conduits 150, 150', 150" joining to one conduit 160 before reaching the receiving vessel 140. As the ash entrained with the carrier gas could deteriorate the operational condition of the control valve, the control valve 54 of Fig. 1 has been replaced by steadier shut-off valves 154, 154', 154" and critical openings 158, 158', 158", like or unlike each other, restricting the gas flow. Naturally, the number of parallel conduits can also be different from three.

[0064] In the embodiment according to Fig. 2, the ash conveying speed can be controlled by opening a necessary number of the shut-off valves 154, 154', 154". If ash is conveyed periodically, the extent of the conveyance can also be regulated by changing the duration of the periods, whereby it is not necessary to have more than one discharge conduit, shut-off valve and critical opening.

[0065] Fig. 3 schematically illustrates the outlet end of the ash conveying system according to a third preferred embodiment of the present invention. In this embodiment, the collecting vessel 230 at the end of the conveyor line is narrow and high, even though its diameter is larger than that of the conveyor line. The proportion of the height of the collecting vessel to its diameter is preferably at least [5] five, most preferably at least [10] ten.

[0066] When conveying ash, an ash column is maintained in the collecting vessel 230 extending preferably at least to the center part of the vessel 230. In the embodiment according to the figure, the ash flow is regulated by a discharge conduit 250 for carrier gas attached to the center part of the collecting vessel 230, in which conduit, the volume of carrier gas 256 can be regulated by a valve 254. At the end of the discharge conduit 250 closest to the collecting vessel 230 is arranged a filter 252 preventing the ash from entering the discharge conduit 250. When the filter 252 is disposed according to the figure inside the ash column flowing downwards, the moving ash simultaneously cleans the outer surface of the filter 252 and prevents the filter 252 from being clogged up.

[0067] Another advantage gained by arranging the first end of the discharge conduit 250 in the area of the ash column is that the portion of the ash column above the joining point of the discharge conduit 250 also acts as a restrictor for the carrier gas flow. Thus, the ash conveyance is partly self-adjusting as the high ash column slows down the gas flow and reduces or even stops the ash conveyance, when the collecting vessel 230 is about to get filled.

[0068] The discharge conduit 250 can also be arranged in the upper part of the collecting vessel 230, whereby it functions in the same way as the discharge conduit 50 according to the first preferred embodiment in Fig. 1. It is also possible to connect the discharge conduit 250 to the lower part of the collecting vessel 230, whereby the flow regulating effect of the ash column is at its highest.

100146604063203

[0069] Fig. 3 also shows another discharge conduit 260 for gas provided with a filter 262 and a control valve 264. The purpose of the discharge conduit 260 is to let the carrier gas 266, discharged from the lower part of the collecting vessel 230, enter the open air without any particular obstruction, i.e., during the ash conveyance, valve 264 does not essentially limit the gas flow. Thus, the lower part of the collecting vessel 230 reaches the atmospheric pressure and the ash 272 can be easily removed from the lower part of the collecting vessel 230 to the receiving vessel (not shown), e.g., by using a rotary feeder 270. The discharge apparatus for ash at the bottom of the collecting vessel 230 can also be of another type, e.g., a conveyor screw or an L-valve. Pressure adjusting in the collecting vessel 230 can also be practiced in many steps, whereby more than the mentioned two discharge conduits 250 for gas are disposed in the collecting vessel 230.

[0070] Fig. 3 also shows a level transmitter 238 provided in the upper part of the collecting vessel 230, and an apparatus 258 for feeding high pressure cleaning pulses to the filters 252 and 262. The collecting vessel 230 can also be used so that the upper surface of the ash column is continuously maintained [on] at a desired predetermined level by using a rotary feeder 270. Another possibility is to use a rotary feeder intermittently, whereby the ash level remains within certain predetermined limits.

[0071] When starting the ash treatment system according to Fig. 3, e.g., sand can be fed to the collecting vessel 230 through a separate conduit not shown in Fig. 3, whereby a sand column restricts the gas flow at the starting stage.

[0072] The invention has just been described in connection with embodiments that are presently considered [as] to be the most preferable[, but]. [it] It must, however, be understood that the invention is not limited to these embodiments [only, but it also]. Rather, it covers a number of other arrangements within the scope of invention determined by the [patent] claims below. [E.g.] For example, a plurality of ash conveyor lines can lead into the same collecting vessel.

[Claims] WE CLAIM:

26. A method of conveying particulate material containing reaction products of a high pressure reactor, from a supply vessel at a pressure of at least two bar to a receiving vessel at a considerably lower pressure, by using an apparatus including a conveyor line attached to the supply vessel and a collecting vessel between the conveyor line and the receiving vessel, wherein the collecting vessel includes a discharge conduit for the carrier gas and means to control the discharge rate of the carrier gas, said method comprising the steps of:

- (a) conveying particulate material from the supply vessel to the collecting vessel pneumatically by using the gas exiting the reactor as a carrier gas, controlling the discharge rate of the carrier gas to control the pressure in the collecting vessel and the flow rate of the particulate material in the conveyor line, and conveying material from the supply vessel to the collecting vessel essentially at the same pressure as is prevailing in the supply vessel;
- (b) reducing pressure of the material collected in the collecting vessel; and
- (c) conveying material from the collecting vessel directly to the receiving vessel essentially at the same pressure as is prevailing in the receiving vessel.

27. A method according to claim 26, further comprising performing step (a) by conveying particulate material as a dense suspension, the flow rate of the carrier gas in the conveyor line being less than 5 m/s and the pressure drop being 0.1 - 1.0 bar.

28. A method according to claim 26, wherein the temperature of the particulate material in the supply vessel is 400 - 1200 °C and further comprising providing the conveyor line with heat exchange surfaces, by which the temperature of the particulate material in step (a) is reduced to less than 300 °C.

10016504.02202

29. A method according to claim 28, further comprising fluidizing the particulate material in the supply vessel by air that is mixed in the carrier gas, thus decreasing the dew point of the carrier gas.

30. A method according to claim 26, further comprising arranging a filter in the discharge conduit for the carrier gas, wherein the means to control the flow rate of the gas includes a control valve downstream from the filter, and discharging in step (a) the carrier gas from the collecting vessel to a space at a pressure which is essentially the same as is prevailing in the receiving vessel.

31. A method according to claim 26, further comprising discharging the carrier gas from the collecting vessel to the receiving vessel in step (a).

32. A method according to claim 31, further comprising providing more than one parallel line for the discharge of the carrier gas between the collecting vessel and the receiving vessel, which lines are provided with a constantly open flow restricting element and a shut-off valve, and performing the control of the discharge velocity by opening and shutting the shut-off valves.

33. A method according to claim 32, wherein the flow restricting elements are easily changeable.

34. A method according to claim 30, wherein the collecting vessel has an elongated form and is arranged in a vertical orientation, and further comprising maintaining a column of particulate material in the collecting vessel, and attaching the discharge conduit for carrier gas to the collecting vessel at the bottom section of the particulate material column.

35. A method according to claim 34, further comprising providing more than one discharge conduit for the carrier gas, the discharge conduits being attached to the collecting vessel at various levels of the particulate material column.

36. A method according to claim 34, further comprising maintaining the pressure in the bottom section of the particulate material column to be approximately the same as is prevailing in the receiving vessel and practicing step (c) intermittently or continuously from the bottom section of the collecting vessel.

37. A method of conveying particulate material according to claim 26, further comprising disposing a gas tight inlet valve in the conveyor line before the collecting vessel and a gas tight discharge valve between the collecting vessel and the receiving vessel, and practicing steps (a) - (c) in alteration, wherein steps (b) and (c) further comprise the sub-steps of:

(b1) stopping the discharge of the carrier gas from the collecting vessel by using the means to control the carrier gas flow, whereby the conveyance of particulate material is stopped;

(b2) closing the shut-off valve before the collecting vessel;

(b3) allowing the discharge of the carrier gas from the collecting vessel until the pressure in the collecting vessel has dropped approximately to the same level as the pressure of the receiving vessel;

(c1) opening the discharge valve and conveying the particulate material from the collecting vessel to the receiving vessel; and

(c2) closing the discharge valve, opening the inlet valve and returning to step (a).

38. A method according to claim 26, further comprising disposing the collecting vessel above the receiving vessel and, in step (c), allowing the particulate material to fall down to the receiving vessel.

100168804 055215

39. A method according to claim 26, further comprising in step (a), periodically changing the flow rate of the carrier gas by stopping the conveyance for a predetermined time at regular intervals or when the pressure in the collecting vessel or the temperature of the material entering the collecting vessel is not within predetermined limits.

40. An apparatus for pneumatically conveying particulate material containing reaction products of a high pressure reactor from a supply vessel at a pressure of at least two bar to a receiving vessel at a considerably lower pressure, said apparatus comprising:

a conveyor line attached to the supply vessel;

a collecting vessel between the conveyor line and the receiving vessel, said collecting vessel comprising (i) a discharge conduit for the carrier gas, (ii) means to control the discharge velocity of the carrier gas from the collecting vessel, and (iii) means to control the pressure of the material collected in the collecting vessel; and

means for conveying the material directly from the collecting vessel to the receiving vessel essentially at the same pressure as is prevailing in the receiving vessel.

41. An apparatus according to claim 40, further comprising heat exchange surfaces disposed in the conveyor line.

42. An apparatus according to claim 41, further comprising disposing elements for fluidizing the particulate material in the supply vessel in such a way that air used for the fluidization is mixed in the carrier gas, thus decreasing the dew point of the carrier gas.

43. An apparatus according to claim 40, further comprising a filter disposed in the discharge conduit for the carrier gas, wherein the means to control the flow rate of the carrier gas includes a control valve arranged downstream from the filter, and the discharge conduit for the carrier gas is in flow communication with the open air.

100188844852202

44. An apparatus according to claim 40, wherein the discharge conduit for the carrier gas is in flow communication with the receiving vessel.

45. An apparatus according to claim 44, further comprising more than one parallel line for the discharge of the carrier gas provided between the collecting vessel and the receiving vessel, which lines are provided with a constantly open flow restricting element and a shut-off valve.

46. An apparatus according to claim 45, wherein the flow restricting elements are easily changeable.

47. An apparatus according to claim 40, wherein the collecting vessel has an elongated form and is disposed in a vertical orientation, and the discharge conduit for the carrier gas is attached to bottom section of the collecting vessel.

48. An apparatus according to claim 47, further comprising more than one discharge conduit for the carrier gas, which are attached to the collecting vessel at various levels.

49. An apparatus according to claim 40, further comprising a gas tight valve disposed in the conveyor line before the collecting vessel and between the collecting vessel and the receiving vessel.

50. An apparatus according to claim 40, wherein the collecting vessel is disposed above the receiving vessel and further comprising a valve arranged between the vessels, through which valve the particulate material may fall down to the receiving vessel.

ABSTRACT

An apparatus for pneumatically conveying particulate material containing reaction products of a high pressure reactor from a supply vessel at a pressure of at least two bar to a receiving vessel at a considerably lower pressure. The apparatus includes a conveyor line attached to the supply vessel, a collecting vessel between the conveyor line and the receiving vessel, the collecting vessel including (i) a discharge conduit for the carrier gas, (ii) a device for controlling the discharge velocity of the carrier gas from the collecting vessel, and (iii) a device for controlling the pressure of the material collected in the collecting vessel, and a device for conveying the material directly from the collecting vessel to the receiving vessel essentially at the same pressure as is prevailing in the receiving vessel.

METHOD AND APPARATUS FOR TREATING HIGH PRESSURE PARTICULATE MATERIAL

5 The present invention relates to a method and an apparatus for treating high pressure particulate material as defined in the preambles of the independent claims.

Thus the invention relates to a method and apparatus for 10 pneumatic conveying of particulate material containing reaction products of a high pressure reactor, by using the gas exiting the reactor as a carrier gas, from a supply vessel at a pressure of at least 2 bar to a receiving vessel at a considerably lower pressure, by using an apparatus comprising 15 a conveyor line and a collecting vessel between the conveyor line and the receiving vessel.

It is generally known to convey solid powdered or granular material by a pneumatic conveyor system. When transported 20 pneumatically, solid material is conveyed in a tubular conveyor line entrained with the carrier gas flowing therein. Pneumatic conveyance is possible for diluted suspensions, whereby a relatively large quantity of gas conveys a relatively small volume of solid material, or for denser 25 suspensions, whereby a relatively small quantity of gas conveys a relatively large volume of solid material.

Pneumatic conveyance is normally performed by feeding 30 superatmospheric carrier gas to a conveyor line or by providing a low pressure in the receiving vessel in the latter end of the conveyor line. Pneumatic conveyance is especially applicable in situations where the supply vessel is for some other reason at a higher pressure than the receiving vessel. Thus it could be possible to utilize the 35 gas in the supply vessel for conveying particulate material

10031004-055202

and it is not necessary to separately arrange carrier gas supply or pressure difference between the vessels.

5 US patent 4,699,210 discloses a system to convey fly ash from a pressurized fluidized bed boiler separated by its particle separator in such a way that the material to be conveyed is led from the bottom portion of the separator to the ash container through a conduit where its flow direction is sharply changed repeated times. Every change of direction 10 consumes energy, whereby the pressure of the flue gas conveying the ash is reduced gradually on its way from the particle separator to the ash container.

15 A drawback in this conveyor system is the clogging of the conveyor line's sharp bends, especially if the ash temperature decreases close to the dew point. To prevent the clogging of the line the ash is conveyed as a thin suspension, whereby the flow rate of the gas needs to be high enough, at least 10 - 15 m/s. This results, however, in high 20 consumption of carrier gas and increases thus the energy consumption substantially. In addition, the high flow rate can cause strong erosion especially at the bends of the line where the direction changes.

25 US patent 4,877,423 discloses a two-stage pneumatic system applicable to conveying and cooling high pressure fly ash, at the first stage of which system, where flue gas is used as a carrier gas, the pressure is reduced only slightly, typically only 0 - 3 bar. In the end section of the first stage is 30 arranged a precipitator to separate flue gas from ash, and a high pressure supply tank for ash. Subsequent to the supply tank the system comprises a lock tank separated by a valve, in which tank the pressure can be reduced to a level required by the further transport and final cooling of the ash.

10016604.022300

The disclosed arrangement with a separate precipitator and two tanks is, however, quite complicated and expensive. Furthermore, the ash discharge of the separator treating the 5 entire ash quantity and having no longer any carrier gas flow, has a tendency to get clogged up, if the ash is adhesive at least to some extent. This prevents the ash from being efficiently cooled at the first stage.

10 It is an object of the present invention to provide a method and apparatus for treating particulate material, in which the above-mentioned prior art problems are minimized.

15 It is a special object of the present invention to provide a simple method and apparatus for controlled pneumatic conveyance and cooling of hot high pressure particulate material.

20 It is a further object of the invention to provide a method and apparatus for pneumatic conveyance of hot high pressure particulate material, in which no overheating and clogging of the conveyor line occur.

25 It is also an object of the invention to provide a method and an apparatus, by which the conveying speed of ash can be controlled and the consumption of carrier gas diminished.

30 In order to solve the above problems a method, the characterizing features of which are disclosed in the characterizing part of the independent method claim, is provided. Thus the method according to the present invention is characterized in that the receiving vessel comprises a discharge conduit for carrier gas and means to control the

100-168004-022222

flow rate of carrier gas and that the method comprises the steps of:

(a) controlling the pressure in the collecting vessel by using the means to control the flow rate of carrier gas so that material is conveyed from the supply vessel to the collecting vessel essentially at the same pressure as is prevailing in the supply vessel, and

(b) conveying material from the collecting vessel to the receiving vessel essentially at the same pressure as is prevailing in the receiving vessel.

In order to solve the above prior art problems an apparatus, the characterizing features of which are disclosed in the characterizing part of the independent apparatus claim, is also provided. Thus the apparatus according to the present invention is characterized in that the receiving vessel comprises a discharge conduit for carrier gas and means to control the discharge velocity of the carrier gas from the collecting vessel, and means to control the pressure of the particulate material collected in the collecting vessel.

The conveyance according to the present invention includes that the flow rate of gas in the conveyor line is preferably relatively low, most preferably less than 5 m/s and particulate material is conveyed as a dense suspension. When the present invention is applied, the frictional forces of the conveyor line are relatively small, whereby the relatively small pressure difference compared to the pressure prevailing in the supply vessel, typically less than 1 bar, between the supply vessel and the collecting vessel, provides a desired flow.

Prior to the conveyance the particulate material may form a thin or a dense layer, e.g. a fluidized bed, in the bottom of

SEARCHED  
INDEXED  
SERIALIZED  
FILED

the supply vessel. The conveyor line may be attached to the supply vessel at the bottom or on the side thereof.

Particulate material can be preferably cooled in the conveyor line by arranging the line at least in some part/-s coaxially so that the particulate material flows in the inner tube and the cooling medium, e.g. water or steam, in the outer tube. A mixer can be also provided between the cooled parts securing that the material is cooled uniformly. The cooling may also be performed or intensified by arranging a heat exchange surface in the supply vessel, collecting vessel or in the receiving vessel.

To prevent clod formation in the conveyed material causing clogging of the conveyor line the material should not be cooled close to the dew point temperature of the carrier gas, i.e., typically, flue gas of a reactor. When utilizing the ash conveyance system according to the present invention, the cooling of the material in the conveyor line can be continued to a lower temperature, if air is added to the carrier gas. Preferably this can be performed by fluidizing the material in the bottom of the supply vessel by air, whereby the flue gas content in the carrier gas is diminished, the partial pressure of water steam and acids is reduced and the dew point of the carrier gas is decreased.

In the method according to the present invention the carrier gas flow from the collecting vessel is adjusted so as to create a desired flow rate for the material between the supply vessel and the collecting vessel. As the discharge conduit for carrier gas is attached to the collecting vessel, the conveyance of the material continues efficiently up to the collecting vessel and the risk that the conveyor line gets clogged up is diminished.

100466054 "DR. BÖHM

In the following some preferred embodiments of the present invention are described as applied to the ash conveyance of a pressurized fluidized bed reactor, but equivalent and other 5 embodiments according to the present invention can be used also in connection with other types of reactors and other particulate materials.

If carrier gas is allowed to discharge from the collecting 10 vessel directly to the open air, a substantial amount of particulate material to be conveyed, e.g. ash, may also be discharged. According to a first preferred embodiment of the invention the carrier gas is allowed to discharge from the collecting vessel through one or more porous filter element/- 15 s. The filter elements can be located inside the collecting vessel or in separate gas discharge pipes outside the collecting vessel. From the filter elements the gas is allowed to discharge to the open air or to another vessel which is substantially at the same pressure as the receiving 20 vessel, e.g. at atmospheric pressure. The gas flow is controlled by the control elements located downstream of the filter elements, which control elements can comprise e.g. a control valve or a combination of an orifice plate and a shut-off valve or a combination of a control valve and a 25 shut-off valve.

The ash entrained with the carrier gas to the filter may 30 disturb or even prevent the gas flow. In order to avoid this, the collecting vessel is formed as a settling vessel, whereby it serves as a preseparator for ash. As a certain amount of ash is in any case entrained with the carrier gas, the filter elements can preferably be cleaned from the material collected on their surface by using high pressure gas pulses.

10016804.DEB2002

According to a second preferred embodiment of the invention the carrier gas is allowed to discharge from the collecting vessel through an orifice of proper size directly to the receiving vessel. Thus the ash entrained with the gas is not 5 allowed to reach the environment but is directed to the receiving vessel. The drawback of this embodiment could be the erosion or plugging of the orifice deriving from ash. To eliminate this problem the orifices are preferably made easily changeable.

10

To control the ash flow rate the gas discharge system comprises preferably two or more parallel gas discharge conduits having an orifice of the same size or of different sizes between the collecting vessel and receiving vessel. The 15 carrier gas discharge conduits are provided with valves, by shutting and opening of which the gas discharge and the ash flow in the conveyor line can be controlled.

As the gas is discharged to the receiving vessel, the 20 receiving vessel needs to be provided with a gas discharge opening, e.g. to the open air, and a filter preventing the ash from exiting through the discharge opening.

The ash conveyor system according to the above preferred 25 first and second embodiments of the present invention is preferably used intermittently, whereby ash is collected in the collecting vessel until its surface reaches a certain predetermined level. After this the ash collected in the collecting vessel is discharged to the receiving vessel.

30

As the receiving vessel is typically at atmospheric pressure or at least essentially at a lower pressure than the collecting vessel during the conveyance of ash, the pressure of the material to be discharged has to be reduced close to

the pressure of the receiving vessel before discharging the collecting vessel. To reduce the pressure in the collecting vessel a shut-off valve can be disposed in the ash conveyor line, preferably at its end closest to the collecting vessel making it possible to separate the collecting vessel from the conveyor line.

Preferably the discharge of the collecting vessel is started by closing the valve controlling the gas exhaust from the collecting vessel. Thus the gas pressure in the conveyor line is increased essentially to the same pressure level as the gas in the supply vessel and the ash flow in the conveyor line is stopped. Next, the shut-off valve arranged in the conveyor line is shut and the valve controlling the discharge of the gas in the collecting vessel is reopened, whereby the gas pressure in the collecting vessel is reduced. When the pressure is low enough, the collected ash is removed from the collecting vessel to the receiving vessel.

20 The collecting vessel can preferably be disposed above the receiving vessel, whereby the ash is allowed to fall directly down to the receiving vessel, after the pressure in the collecting vessel has been allowed to fall to the same level as the pressure in the receiving vessel.

25 The ash can be conveyed from the collecting vessel to the receiving vessel also by other means, e.g. by using a screw or pneumatically, whereby the pressure in the collecting vessel can remain even slightly higher than the pressure in  
30 the receiving vessel, when the pressure is reduced, and the carrier gas can be used for conveying the ash to the receiving vessel.

The essential idea of the present invention is that the valve disposed in the conveyor line is not used for controlling the ash conveying speed, but only for separating the collecting vessel from the conveyor line after the ash flow has been 5 stopped by the valves controlling the gas discharge.

The valves controlling the gas exhaust can preferably be used not only for stopping the ash conveyance for the discharge of the collecting vessel, but also for controlling the ash 10 conveying speed. It is especially preferable to change the conveying speed intermittently, e.g. so that the conveyance is performed essentially at constant speed, but is stopped completely at regular intervals. Thus excessive rising or falling of temperature as well as the generation of 15 agglomerations disturbing the conveyance can be prevented. If ash is collected only to a minor extent, even carrier gas can be saved by using intermittent ash conveyance thus improving the efficiency of the plant.

20 Intermittent stopping of the ash conveyance can be controlled on the basis of certain variables measured in the conveyance system. The ash conveyance can be stopped e.g. when the temperature of the ash entering the collecting vessel or the pressure difference between the supply vessel and collecting 25 vessel is too high or too low. Too high a temperature indicates that the volume of ash to be conveyed is so large that the cooling has no time to reduce its temperature sufficiently. Too high a pressure difference indicates that the line might be about to get plugged and the gas discharge 30 from the collecting vessel has to be temporarily shut in order to control the situation.

On the other hand, too low a pressure difference or a temperature of the entering ash can indicate that the ash

conveyance is insignificant, probably for the reason that there is no ash in the supply vessel. In this case the conveyance should be temporarily stopped in order to save carrier gas and energy. Excessive cooling of the ash also 5 increases the risk of plugging of the conveyor line. The temperature of the ash entering the collecting vessel is preferably less than 300 °C, more preferably 100 - 200 °C. The pressure difference between the supply vessel and the collecting vessel is preferably 0.1 - 1.0 bar or less than 10 0.3 bar for each 10 m of the conveyor line.

The conveyor systems according to the above-described first and second embodiments of the present invention can be used e.g. for conveying fly ash separated by a flue gas filter 15 unit of a pressurized fluidized bed reactor used for combustion or gasification of material.

According to a third preferred embodiment of the present invention the collecting vessel has a tubular form and it is 20 arranged in a vertical position so that ash enters the collecting vessel through its upper part. Typically, the proportion of the height and the diameter of the collecting vessel is at least 5, more preferably at least 10, but it can preferably be even over 30. Thus the first gas discharge pipe 25 provided with a filter is preferably disposed in the lower part of the vessel and the ash discharge system in the bottom of the vessel. There are possibly a plurality of gas discharge pipes at various levels of the vessel. The filter attached to the discharge pipes can preferably be arranged inside the 30 tubular collecting vessel in contact with the material to be conveyed.

When using the ash discharge system according to the third preferred embodiment, the ash disposal from the collecting

vessel is preferably controlled by an ash column having an approximately constant height in the tubular collecting vessel. As the carrier gas passes through the ash column, its pressure falls without any separate means so that ash can be removed from the lower part of the collecting vessel, directly to an ash container, e.g. at atmospheric pressure. This kind of a conveyance system is particularly suitable for removing coarse bottom ash, e.g. from the furnace of a fluidized bed reactor used for combustion or gasification of material.

10 The collecting vessel according to the above-described third embodiment can also be dimensioned so that it has a self-adjusting overfill protector. Thus the diameter and the height of the vessel have to be such that the airflow through the ash 15 column slows down essentially before the ash column in the vessel is too high, whereby the ash conveyance to the collecting vessel is reduced or even stopped completely.

In all above-described embodiments the conveyor line comprises parts that can be oriented with any desired position, i.e. vertical, horizontal or oblique. If necessary, the flow of the particulate material in the conveyor line, especially where the line is bent, can be assisted by introducing small quantities of carrier gas, e.g. air, into the line continuously or intermittently.

The invention is characterized in that there are no valves for controlling the conveying speed of the ash in the ash conveyor line. There can be shut-off valves in the line intended to be used when a part of the system needs to be separated from the others, e.g. for maintenance.

In the following the invention will be described more closely with reference to the accompanying drawings, in which

卷之三

Fig. 1 schematically illustrates an ash conveying system according to a first preferred embodiment of the present invention;

5

Fig. 2 schematically illustrates the outlet end of the ash conveying system according to a second preferred embodiment of the present invention;

10 Fig. 3 schematically illustrates the outlet end of the ash conveying system according to a third preferred embodiment of the present invention;

15 Fig. 1 illustrates an ash conveying system according to a first preferred embodiment of the present invention, the supply vessel 10, ash conveyor line 20 and receiving vessel 40 of which can be similar to those even in other preferred embodiments. The various embodiments differ from each other mainly in how the carrier gas discharge from the collecting 20 vessel 30 and the pressure reduction of the collected material are arranged.

25 The invention is characterized in that particulate material containing reaction products of a reactor is conveyed pneumatically from a supply vessel 10 at a pressure of at least 2 bar, typically at 6 - 20 bar, to a receiving vessel 40, e.g. at atmospheric pressure, using the gas exiting the reactor as a carrier gas. When applying the invention the volume of the supply vessel is typically larger than the 30 volume of the conveyor line and it can be assumed that the pressure of the supply vessel is constant.

The supply vessel 10 can consist e.g. of a bottom part of a filter for fly ash from a high pressure fluidized bed reactor

or it can be a part of the removal system for bottom ash from a fluidized bed reactor. In the former case the ash 12 collected in the supply vessel is powdered, compressible fly ash, whereas in the latter case the ash could be coarse. The 5 quality of the ash to be conveyed has to be considered when choosing the embodiment and the method, by which the system according to the present invention is applied.

In the supply vessel the ash temperature is typically 400 - 10 1200 °C and for precooling the ash the vessel can be provided with heat exchange surfaces 14, e.g. heat exchange pipes, in which water or steam circulates.

The ash is conveyed in a tubular conveyor line 20, in which a 15 heat exchange surface could be arranged, e.g. a sleeve 22 covering the line at least partly and having means 24, 25 for the recirculation of heat exchange medium, e.g. water or steam. By the heat exchange surfaces 22 the ash temperature can be reduced, e.g. to 150 - 300 °C.

20 It is possible to arrange means 16 for the introduction of fluidizing gas, e.g. air, at the bottom of the supply vessel. These can prevent the clogging of the lower part of the collecting vessel deriving from the arching of ash. Further, 25 fluidizing air can be mixed in the carrier gas used in the conveyance, and reduce its dew point. Thus the clogging of the conveyor line due to moistening as the result of ash cooling can be prevented.

30 In Fig. 1 the conveyor line 20 starts below the supply vessel, turns upwards after the horizontal section and leads again horizontally above the collecting vessel 30. In practice, the conveyor line can consist of parts with any desired position. To avoid the clogging of the line it could

be occasionally or continuously necessary to add small quantities of carrier gas 28, e.g. air, to some points of the line, especially to the bent sections.

5 The ash conveyor line 20 ends in the collecting vessel 30, to which a discharge conduit 50 for carrier gas is attached. The conveyor line 20 is preferably formed of an extension part 32 extending slightly into the collecting vessel and directing the ash towards the bottom of the collecting vessel 30 thus  
10 reducing the probability of the ash being entrained with the gas to the discharge conduit 50. The collecting vessel 30 is also formed so as to reduce the speed of the carrier gas essentially when flowing from the extension part 32 of the conveyor line 20 to the collecting vessel. Thus the  
15 collecting vessel serves as a settling chamber for ash separating a substantial part of the ash conveyed by the carrier gas.

In the embodiment according to Fig. 1 the discharge conduit  
20 50 is provided with a filter 52 and a control valve 54 for controlling the flow rate of the discharged carrier gas 56. The discharge conduit leads preferably to the open air or to a space essentially at atmospheric pressure. If the pressure  
25 of the receiving vessel differs from the atmospheric pressure, it is preferable to draw the discharge conduit 50 to a space essentially at the same pressure as the receiving vessel.

As ash can be entrained with the carrier gas to the filter  
30 52, the filter is provided with means 60 for cleaning the filter by giving intermittent gas pulses to the clean side thereof.

10014582014 052500

In the embodiment according to Fig. 1 the collecting vessel 30 is arranged immediately above the receiving vessel 40. The collecting vessel 30 is separated from the receiving vessel 40 by a gas tight valve 34. There is also a gas tight valve 5 36 between the collecting vessel 30 and the conveyor line 20.

The present invention is characterized in that the gas discharge speed is adjusted by a control valve 54 so as to convey ash in the line 20 as a dense suspension the flow rate 10 of the carrier gas being less than 5 m/s. Thus the erosion and consumption of carrier gas caused by the conveyance are relatively insignificant. Valve 34 is shut and valve 36 is open during the conveyance. It is to be noted that valve 36 is not used for controlling the conveying speed of the ash or 15 for stopping thereof.

In the technical solution according to Fig. 1 a valve 18 is also arranged between the supply vessel 10 and the conveyor line 20. The system may include such a valve and possibly 20 even other valves not marked in the figure, as they do not have any significance from the viewpoint of the present invention. Valve 18 could be needed e.g. when maintaining the system, but in normal operation the valve is open.

25 When the level transmitter 38 attached to the collecting vessel 30 indicates that the collecting vessel is about to get filled, the ash conveyance is stopped. The carrier gas flow is stopped by shutting valve 54. When the ash conveyance is stopped, valve 36 is shut. After this, valve 54 is 30 reopened and the pressure of the collecting vessel is allowed to fall so that it is essentially the same as the pressure of the receiving vessel and the ash can fall down into the receiving vessel by opening the valve 34.

To restart the ash conveyance, valve 34 is shut, valve 36 is opened and the ash flow rate is adjusted by valve 54 to a desired value. To protect valve 36, it could be necessary to raise the pressure of the collecting vessel essentially to 5 the same level as that of the supply vessel 10. This can preferably be performed by using a system 60 producing cleaning pulses for the filter 52 of the discharge conduit 50. Simultaneously, the filter is also cleaned from ash possibly collected on its surface at the preceding filling 10 stage of the collecting vessel. The receiving vessel can be provided with heat exchange surfaces 44 for the final cooling of the ash as well as with an opening for ash discharge 46 in the bottom of the vessel.

15 The ash conveyance system according to the present invention is preferably used intermittently also between the discharges of the collecting vessel 30 so that the temperature  $T_1$  of the ash entering the collecting vessel 30 at the end of the conveyor line 20 and the pressure difference  $\Delta p$  between the 20 supply vessel and the collecting vessel are monitored. When  $T_1$  or  $\Delta p$  is not within the predetermined limits, the discharge of carrier gas and the ash conveyance are stopped by valve 54. Sometimes it could be sufficient to perform the 25 ash conveyance in a predetermined way intermittently. The ash conveyance can also be stopped when it is detected that the volume of ash in the supply vessel falls below a predetermined level.

30 Fig. 2 schematically illustrates the outlet end of the ash conveying system according to a second preferred embodiment of the present invention. There the collecting vessel 130, receiving vessel 140, valves 136 and 134 and the parts missing in the figure are similar to those in the embodiment

10016804.000202

according to Fig. 1. The operational principle of this embodiment is also similar to that of the embodiment according to Fig. 1.

5 The second preferred embodiment according to Fig. 2 differs from the first preferred embodiment according to Fig. 1 in that the discharge conduit for carrier gas is in communication with the receiving vessel 140. Thus also the ash entrained with the carrier gas is led to the receiving  
10 vessel 140. Naturally, when using the second preferred embodiment according to Fig. 2, the receiving vessel has to be provided with a discharge conduit 162 for gas, e.g. to the open air, and a filter 162 preventing the ash from being entrained out with the gas.

15 In the embodiment according to Fig. 2 the discharge conduit is divided into three parallel conduits 150, 150' and 150'' joining to one conduit 160 before reaching the receiving vessel 140. As the ash entrained with the carrier gas could deteriorate the operational condition of the control valve, the control valve 54 of Fig. 1 has been replaced by steadier shut-off valves 154, 154', 154'' and critical openings 158, 158', 158'', like or unlike each other, restricting the gas flow. Naturally the number of parallel conduits can also be  
20 25 different from three.

In the embodiment according to Fig. 2 the ash conveying speed can be controlled by opening a necessary number of the shut-off valves 154, 154', 154''. If ash is conveyed periodically, the extent of the conveyance can also be regulated by changing the duration of the periods, whereby it is not necessary to have more than one discharge conduit, shut-off valve and critical opening.

10016664 DESSO

Fig. 3 schematically illustrates the outlet end of the ash conveying system according to a third preferred embodiment of the present invention. In this embodiment the collecting vessel 230 at the end of the conveyor line is narrow and 5 high, even though its diameter is larger than that of the conveyor line. The proportion of the height of the collecting vessel to its diameter is preferably at least 5, most preferably at least 10.

10 When conveying ash, an ash column is maintained in the collecting vessel extending preferably at least to the center part of the vessel. In the embodiment according to the figure the ash flow is regulated by a discharge conduit 250 for carrier gas attached to the center part of the collecting 15 vessel, in which conduit the volume of carrier gas 256 can be regulated by a valve 254. At the end of the discharge conduit closest to the collecting vessel is arranged a filter 252 preventing the ash from entering the discharge conduit 250. When the filter is disposed according to the figure inside 20 the ash column flowing downwards, the moving ash simultaneously cleans the outer surface of the filter and prevents the filter from being clogged up.

Another advantage gained by arranging the first end of the 25 discharge conduit in the area of the ash column is that the portion of the ash column above the joining point of the discharge conduit also acts as a restrictor for the carrier gas flow. Thus the ash conveyance is partly self-adjusting as the high ash column slows down the gas flow and reduces or 30 even stops the ash conveyance, when the collecting vessel is about to get filled.

The discharge conduit 250 can also be arranged in the upper part of the collecting vessel, whereby it functions in the

same way as the discharge conduit according to the first preferred embodiment in Fig. 1. It is also possible to connect the discharge conduit 250 to the lower part of the collecting vessel 230, whereby the flow regulating effect of  
5 the ash column is at its highest.

Fig. 3 also shows another discharge conduit 260 for gas provided with a filter 262 and a control valve 264. The purpose of the discharge conduit 260 is to let the carrier  
10 gas 266 discharged from the lower part of the collecting vessel enter the open air without any particular obstruction, i.e. during the ash conveyance valve 264 does not essentially limit the gas flow. Thus the lower part of the collecting vessel 230 reaches the atmospheric pressure and the ash 272  
15 can be easily removed from the lower part of the collecting vessel to the receiving vessel, e.g. by using a rotary feeder 270. The discharge apparatus for ash at the bottom of the collecting vessel can also be another, e.g. a conveyor screw or an L-valve. Pressure adjusting in the collecting vessel  
20 can also be practiced in many steps, whereby more than the mentioned two discharge conduits for gas are disposed in the collecting vessel.

Fig. 3 also shows a level transmitter 238 provided in the  
25 upper part of the collecting vessel, and an apparatus 258 for feeding high pressure cleaning pulses to the filters 252 and 262. The collecting vessel can also be used so that the upper surface of the ash column is continuously maintained on a desired predetermined level by using a rotary feeder 270.  
30 Another possibility is to use a rotary feeder intermittently, whereby the ash level remains within certain predetermined limits.

When starting the ash treatment system according to Fig. 3, e.g. sand can be fed to the collecting vessel through a separate conduit not shown in Fig. 3, whereby a sand column restricts the gas flow at the starting stage.

5

The invention has just been described in connection with embodiments that are presently considered as the most preferable, but it must, however, be understood that the invention is not limited to these embodiments only, but it 10 also covers a number of other arrangements within the scope of invention determined by the patent claims below. E.g. a plurality of ash conveyor lines can lead into the same collecting vessel.

## Claims

1. Method of conveying particulate material containing reaction products of a high pressure reactor, from a supply vessel at a pressure of at least 2 bar to a receiving vessel at a considerably lower pressure, by using an apparatus comprising a conveyor line attached to the supply vessel and a collecting vessel between the conveyor line and the receiving vessel, where said collecting vessel comprises a discharge conduit for carrier gas and means to control the discharge rate of the carrier gas, said method comprising the step of

5 (a) conveying particulate material from the supply vessel to the collecting vessel pneumatically by using the gas exiting the reactor as a carrier gas, and controlling the discharge rate of the carrier gas to control the pressure in

10 the collecting vessel and the flow rate of the particulate material in the conveyor line,

15 characterized in that in step (a) material is conveyed from the supply vessel to the collecting vessel essentially at the same pressure as is prevailing in the supply vessel, and that the method comprises the further steps of

20 (b) reducing pressure of the material collected in the collecting vessel, and

25 (c) conveying material from the collecting vessel directly to the receiving vessel essentially at the same pressure as is prevailing in the receiving vessel.

2. Method of conveying particulate material according to claim 1, characterized in that step (a) is practiced by conveying particulate material as a dense suspension the flow rate of the carrier gas in the conveyor line being less than 5 m/s and the pressure drop 0.1 - 1.0 bar.

PCT/GB96/002202

3. Method of conveying particulate material according to claim 1, characterized in that the temperature of the particulate material in the supply vessel is 400 - 1200 °C and the conveyor line is provided with heat exchange surfaces, by which the temperature of the particulate material in step (a) is reduced to less than 300 °C.

4. Method of conveying particulate material according to claim  
3, characterized in that the particulate material in the  
10 supply vessel is fluidized by air that is mixed in the carrier  
gas decreasing the dew point thereof.

15 5. Method of conveying particulate material according to claim  
1, characterized in that a filter is arranged in the discharge  
conduit for carrier gas, the means to control the flow rate of  
the gas includes a control valve downstream from the filter,  
and in step (a) the carrier gas is discharged from the  
collecting vessel to a space at the pressure which is  
essentially the same as is prevailing in the receiving vessel.

20 6. Method of conveying particulate material according to claim  
1, characterized in that the carrier gas is discharged from  
the collecting vessel to the receiving vessel in step (a).

25 7. Method of conveying particulate material according to claim  
6, characterized in that more than one parallel lines for the  
discharge of carrier gas are provided between the collecting  
vessel and the receiving vessel, which lines are provided with  
a constantly open flow restricting element and a shut-off  
30 valve, and the control of the discharge velocity is performed  
by opening and shutting the shut-off valves.

8. Method of conveying particulate material according to claim 7, characterized in that the flow restricting elements are easily changeable.

5 9. Method of conveying particulate material according to claim 5, characterized in that the collecting vessel has an elongated form and it is arranged in a vertical position, and a column of particulate material is maintained in the collecting vessel, and the discharge conduit for carrier gas  
10 is attached to the collecting vessel at the bottom section of the particulate material column.

10. Method of conveying particulate material according to claim 9, characterized in that more than one discharge conduit  
15 for carrier gas are provided and these are attached to the collecting vessel at various levels of the particulate material column.

20 11. Method of conveying particulate material according to claim 9, characterized in that the pressure in the bottom section of the particulate material column is approximately the same as is prevailing in the receiving vessel and step (c) is practiced intermittently or continuously from the bottom section of the collecting vessel.

25 12. Method of conveying particulate material according to claim 1, characterized in that a gas tight inlet valve is disposed in the conveyor line before the collecting vessel and a gas tight discharge valve is disposed between the collecting  
30 vessel and the receiving vessel, and steps (a) - (c) are practiced in alteration steps (b) and (c) comprising the sub-steps of:

00046604-000200

(b1) stopping the discharge of carrier gas from the collecting vessel by using the means to control the carrier gas flow, whereby the conveyance of particulate material is stopped;

(b2) closing the shut-off valve before the collecting vessel;

5 (b3) allowing the discharge of carrier gas from the collecting vessel until the pressure in the collecting vessel has dropped approximately to the same level as the pressure of the receiving vessel;

10 (c1) opening the discharge valve and conveying the particulate material from the collecting vessel to the receiving vessel; and

(c2) closing the discharge valve, opening the inlet valve and returning to step (a).

15 13. Method of conveying particulate material according to claim 1, characterized in that the collecting vessel is disposed above the receiving vessel and in step (c) the particulate material is allowed to fall down to the receiving vessel.

20 14. Method of conveying particulate material according to claim 1, characterized in that in step (a) the flow rate of the carrier gas is periodically changed by stopping the conveyance for a predetermined time at regular intervals or 25 when the pressure in the collecting vessel or the temperature of the material entering the collecting vessel is not within predetermined limits.

30 15. Apparatus for pneumatic conveying of particulate material containing reaction products of a high pressure reactor from a supply vessel at a pressure of at least 2 bar to a receiving vessel at a considerably lower pressure, said apparatus comprising a conveyor line attached to the supply vessel and a collecting vessel between the conveyor line and the receiving

100-16805-162-02

vessel, where said collecting vessel comprises a discharge conduit for carrier gas and means to control the discharge velocity of the carrier gas from the collecting vessel, characterized in that the collecting vessel comprises means to control the pressure of the material collected in the collecting vessel, and said apparatus comprises means for conveying the material directly from the collecting vessel to the receiving vessel essentially at the same pressure as is prevailing in the receiving vessel.

10

16. Apparatus for conveying particulate material according to claim 15, characterized in that heat exchange surfaces are disposed in the conveyor line.

15

17. Apparatus for conveying particulate material according to claim 16, characterized in that elements for fluidizing the particulate material are disposed in the supply vessel in such a way that air used for the fluidization is mixed in the carrier gas thus decreasing the dew point of the carrier gas.

20

18. Apparatus for conveying particulate material according to claim 15, characterized in that a filter is disposed in the discharge conduit for carrier gas, the means to control the flow rate of the carrier gas including a control valve is arranged downstream from the filter, and the discharge conduit for carrier gas is in flow communication with the open air.

30

19. Apparatus for conveying particulate material according to claim 15, characterized in that the discharge conduit for carrier gas is in flow communication with the receiving vessel.

20. Apparatus for conveying particulate material according to claim 19, characterized in that more than one parallel lines

10016005-00000000

for the discharge of carrier gas are provided between the collecting vessel and the receiving vessel, which lines are provided with a constantly open flow restricting element and a shut-off valve.

5

21. Apparatus for conveying particulate material according to claim 20, characterized in that the flow restricting elements are easily changeable.

10 22. Apparatus for conveying particulate material according to claim 15, characterized in that the collecting vessel has an elongated form and it is disposed in a vertical position, and the discharge conduit for carrier gas is attached to bottom section of the collecting vessel.

15

23. Apparatus for conveying particulate material according to claim 22, characterized in that more than one discharge conduit for carrier gas are provided and these are attached to the collecting vessel at various levels.

20

24. Apparatus for conveying particulate material according to claim 15, characterized in that a gas tight valve is disposed in the conveyor line before the collecting vessel and between the collecting vessel and the receiving vessel.

25

25. Apparatus for conveying particulate material according to claim 15, characterized in that the collecting vessel is disposed above the receiving vessel and a valve is arranged between the vessels, through which valve the particulate material may fall down to the receiving vessel.

METHOD AND APPARATUS FOR TREATING HIGH PRESSURE PARTICULATE  
MATERIAL

5 The present invention relates to a method and an apparatus for treating high pressure particulate material as defined in the preambles of the independent claims.

Thus the invention relates to a method and apparatus for  
10 pneumatic conveying of particulate material containing reaction products of a high pressure reactor, by using the gas exiting the reactor as a carrier gas, from a supply vessel at a pressure of at least 2 bar to a receiving vessel at a considerably lower pressure, by using an apparatus comprising  
15 a conveyor line and a collecting vessel between the conveyor line and the receiving vessel.

It is generally known to convey solid powdered or granular material by a pneumatic conveyor system. When transported  
20 pneumatically, solid material is conveyed in a tubular conveyor line entrained with the carrier gas flowing therein. Pneumatic conveyance is possible for diluted suspensions, whereby a relatively large quantity of gas conveys a relatively small volume of solid material, or for denser  
25 suspensions, whereby a relatively small quantity of gas conveys a relatively large volume of solid material.

Pneumatic conveyance is normally performed by feeding superatmospheric carrier gas to a conveyor line or by  
30 providing a low pressure in the receiving vessel in the latter end of the conveyor line. Pneumatic conveyance is especially applicable in situations where the supply vessel is for some other reason at a higher pressure than the receiving vessel. Thus it could be possible to utilize the  
35 gas in the supply vessel for conveying particulate material

10018804.P00000

and it is not necessary to separately arrange carrier gas supply or pressure difference between the vessels.

US patent 4,699,210 discloses a system to convey fly ash from a pressurized fluidized bed boiler separated by its particle separator in such a way that the material to be conveyed is led from the bottom portion of the separator to the ash container through a conduit where its flow direction is sharply changed repeated times. Every change of direction consumes energy, whereby the pressure of the flue gas conveying the ash is reduced gradually on its way from the particle separator to the ash container.

A drawback in this conveyor system is the clogging of the conveyor line's sharp bends, especially if the ash temperature decreases close to the dew point. To prevent the clogging of the line the ash is conveyed as a thin suspension, whereby the flow rate of the gas needs to be high enough, at least 10 - 15 m/s. This results, however, in high consumption of carrier gas and increases thus the energy consumption substantially. In addition, the high flow rate can cause strong erosion especially at the bends of the line where the direction changes.

US patent 4,877,423 discloses a two-stage pneumatic system applicable to conveying and cooling high pressure fly ash, at the first stage of which system, where flue gas is used as a carrier gas, the pressure is reduced only slightly, typically only 0 - 3 bar. In the end section of the first stage is arranged a precipitator to separate flue gas from ash, and a high pressure supply tank for ash. Subsequent to the supply tank the system comprises a lock tank separated by a valve, in which tank the pressure can be reduced to a level required by the further transport and final cooling of the ash.

100118804.052502

2a

The disclosed arrangement with a separate precipitator and two tanks is, however, quite complicated and expensive. Furthermore, the ash discharge of the separator treating the entire ash quantity and having no longer any carrier gas flow, has a tendency to get clogged up, if the ash is adhesive at least to some extent. This prevents the ash from being efficiently cooled at the first stage.

10 European patent 0 582 049 discloses a system for  
depressurizing and conveying particulate materials, where the  
solids flow rate in the pneumatic conveyor line is controlled  
by changing the cross section of a choke means and/or by  
changing the pressure in a reservoir upstream the conveyor  
15 line. The material is also depressurized by the mechanical  
choke means.

US patent 5,707,198 discloses a system for discharging particulate material from a first container to a lower positioned, lower pressure storage area. The quantity of material discharged to the storage area is controlled by a material feeder. The pressure of the material is reduced in the material columns formed in an upper tube section between the first container and a pressure stabilizer and a lower tube section between the pressure stabilizer and the feeder.

Japanese patent publication JP 07042910 discloses a system for pneumatic conveying of particulate material, where the material is first conveyed to a high pressure ash storing device, from where it is transferred to a separate hopper in order to reduce the pressure to the atmospheric pressure, and then the material is finally transferred to a normal pressure hopper.

~~The disclosed arrangement with a separate precipitator and two tanks is, however, quite complicated and expensive. Furthermore, the ash discharge of the separator treating the entire ash quantity and having no longer any carrier gas flow, has a tendency to get clogged up, if the ash is adhesive at least to some extent. This prevents the ash from being efficiently cooled at the first stage.~~

10 It is an object of the present invention to provide a method and apparatus for treating particulate material, in which the above-mentioned prior art problems are minimized.

15 It is a special object of the present invention to provide a simple method and apparatus for controlled pneumatic conveyance and cooling of hot high pressure particulate material.

20 It is a further object of the invention to provide a method and apparatus for pneumatic conveyance of hot high pressure particulate material, in which no overheating and clogging of the conveyor line occur.

25 It is also an object of the invention to provide a method and an apparatus, by which the conveying speed of ash can be controlled and the consumption of carrier gas diminished.

30 In order to solve the above problems a method, the characterizing features of which are disclosed in the characterizing part of the independent method claim, is provided. Thus the method according to the present invention is characterized in that the receiving vessel comprises a discharge conduit for carrier gas and means to control the

flow rate of carrier gas and that the method comprises the steps of:

(a) controlling the pressure in the collecting vessel by using the means to control the flow rate of carrier gas so that material is conveyed from the supply vessel to the collecting vessel essentially at the same pressure as is prevailing in the supply vessel, and

(b) conveying material from the collecting vessel to the receiving vessel essentially at the same pressure as is prevailing in the receiving vessel.

In order to solve the above prior art problems an apparatus, the characterizing features of which are disclosed in the characterizing part of the independent apparatus claim, is also provided. Thus the apparatus according to the present invention is characterized in that the receiving vessel comprises a discharge conduit for carrier gas and means to control the discharge velocity of the carrier gas from the collecting vessel, and means to control the pressure of the particulate material collected in the collecting vessel.

The conveyance according to the present invention includes that the flow rate of gas in the conveyor line is preferably relatively low, most preferably less than 5 m/s and particulate material is conveyed as a dense suspension. When the present invention is applied, the frictional forces of the conveyor line are relatively small, whereby the relatively small pressure difference compared to the pressure prevailing in the supply vessel, typically less than 1 bar, between the supply vessel and the collecting vessel, provides a desired flow.

Prior to the conveyance the particulate material may form a thin or a dense layer, e.g. a fluidized bed, in the bottom of

the supply vessel. The conveyor line may be attached to the supply vessel at the bottom or on the side thereof.

Particulate material can be preferably cooled in the conveyor line by arranging the line at least in some part/-s coaxially so that the particulate material flows in the inner tube and the cooling medium, e.g. water or steam, in the outer tube. A mixer can be also provided between the cooled parts securing that the material is cooled uniformly. The cooling may also be performed or intensified by arranging a heat exchange surface in the supply vessel, collecting vessel or in the receiving vessel.

To prevent clod formation in the conveyed material causing clogging of the conveyor line the material should not be cooled close to the dew point temperature of the carrier gas, i.e., typically, flue gas of a reactor. When utilizing the ash conveyance system according to the present invention, the cooling of the material in the conveyor line can be continued to a lower temperature, if air is added to the carrier gas. Preferably this can be performed by fluidizing the material in the bottom of the supply vessel by air, whereby the flue gas content in the carrier gas is diminished, the partial pressure of water steam and acids is reduced and the dew point of the carrier gas is decreased.

In the method according to the present invention the carrier gas flow from the collecting vessel is adjusted so as to create a desired flow rate for the material between the supply vessel and the collecting vessel. As the discharge conduit for carrier gas is attached to the collecting vessel, the conveyance of the material continues efficiently up to the collecting vessel and the risk that the conveyor line gets clogged up is diminished.

In the following some preferred embodiments of the present invention are described as applied to the ash conveyance of a pressurized fluidized bed reactor, but equivalent and other 5 embodiments according to the present invention can be used also in connection with other types of reactors and other particulate materials.

If carrier gas is allowed to discharge from the collecting 10 vessel directly to the open air, a substantial amount of particulate material to be conveyed, e.g. ash, may also be discharged. According to a first preferred embodiment of the invention the carrier gas is allowed to discharge from the collecting vessel through one or more porous filter element/- 15 s. The filter elements can be located inside the collecting vessel or in separate gas discharge pipes outside the collecting vessel. From the filter elements the gas is allowed to discharge to the open air or to another vessel which is substantially at the same pressure as the receiving 20 vessel, e.g. at atmospheric pressure. The gas flow is controlled by the control elements located downstream of the filter elements, which control elements can comprise e.g. a control valve or a combination of an orifice plate and a shut-off valve or a combination of a control valve and a 25 shut-off valve.

The ash entrained with the carrier gas to the filter may disturb or even prevent the gas flow. In order to avoid this, the collecting vessel is formed as a settling vessel, whereby 30 it serves as a preseparator for ash. As a certain amount of ash is in any case entrained with the carrier gas, the filter elements can preferably be cleaned from the material collected on their surface by using high pressure gas pulses.

According to a second preferred embodiment of the invention the carrier gas is allowed to discharge from the collecting vessel through an orifice of proper size directly to the receiving vessel. Thus the ash entrained with the gas is not allowed to reach the environment but is directed to the receiving vessel. The drawback of this embodiment could be the erosion or plugging of the orifice deriving from ash. To eliminate this problem the orifices are preferably made easily changeable.

10

To control the ash flow rate the gas discharge system comprises preferably two or more parallel gas discharge conduits having an orifice of the same size or of different sizes between the collecting vessel and receiving vessel. The carrier gas discharge conduits are provided with valves, by shutting and opening of which the gas discharge and the ash flow in the conveyor line can be controlled.

As the gas is discharged to the receiving vessel, the receiving vessel needs to be provided with a gas discharge opening, e.g. to the open air, and a filter preventing the ash from exiting through the discharge opening.

25 The ash conveyor system according to the above preferred first and second embodiments of the present invention is preferably used intermittently, whereby ash is collected in the collecting vessel until its surface reaches a certain predetermined level. After this the ash collected in the collecting vessel is discharged to the receiving vessel.

30

As the receiving vessel is typically at atmospheric pressure or at least essentially at a lower pressure than the collecting vessel during the conveyance of ash, the pressure of the material to be discharged has to be reduced close to

the pressure of the receiving vessel before discharging the collecting vessel. To reduce the pressure in the collecting vessel a shut-off valve can be disposed in the ash conveyor line, preferably at its end closest to the collecting vessel 5 making it possible to separate the collecting vessel from the conveyor line.

Preferably the discharge of the collecting vessel is started by closing the valve controlling the gas exhaust from the 10 collecting vessel. Thus the gas pressure in the conveyor line is increased essentially to the same pressure level as the gas in the supply vessel and the ash flow in the conveyor line is stopped. Next, the shut-off valve arranged in the conveyor line is shut and the valve controlling the discharge 15 of the gas in the collecting vessel is reopened, whereby the gas pressure in the collecting vessel is reduced. When the pressure is low enough, the collected ash is removed from the collecting vessel to the receiving vessel.

20 The collecting vessel can preferably be disposed above the receiving vessel, whereby the ash is allowed to fall directly down to the receiving vessel, after the pressure in the collecting vessel has been allowed to fall to the same level as the pressure in the receiving vessel.

25 The ash can be conveyed from the collecting vessel to the receiving vessel also by other means, e.g. by using a screw or pneumatically, whereby the pressure in the collecting vessel can remain even slightly higher than the pressure in 30 the receiving vessel, when the pressure is reduced, and the carrier gas can be used for conveying the ash to the receiving vessel.

The essential idea of the present invention is that the valve disposed in the conveyor line is not used for controlling the ash conveying speed, but only for separating the collecting vessel from the conveyor line after the ash flow has been 5 stopped by the valves controlling the gas discharge.

The valves controlling the gas exhaust can preferably be used not only for stopping the ash conveyance for the discharge of the collecting vessel, but also for controlling the ash 10 conveying speed. It is especially preferable to change the conveying speed intermittently, e.g. so that the conveyance is performed essentially at constant speed, but is stopped completely at regular intervals. Thus excessive rising or falling of temperature as well as the generation of 15 agglomerations disturbing the conveyance can be prevented. If ash is collected only to a minor extent, even carrier gas can be saved by using intermittent ash conveyance thus improving the efficiency of the plant.

20 Intermittent stopping of the ash conveyance can be controlled on the basis of certain variables measured in the conveyance system. The ash conveyance can be stopped e.g. when the temperature of the ash entering the collecting vessel or the pressure difference between the supply vessel and collecting 25 vessel is too high or too low. Too high a temperature indicates that the volume of ash to be conveyed is so large that the cooling has no time to reduce its temperature sufficiently. Too high a pressure difference indicates that the line might be about to get plugged and the gas discharge 30 from the collecting vessel has to be temporarily shut in order to control the situation.

On the other hand, too low a pressure difference or a temperature of the entering ash can indicate that the ash

50018804.002502

conveyance is insignificant, probably for the reason that there is no ash in the supply vessel. In this case the conveyance should be temporarily stopped in order to save carrier gas and energy. Excessive cooling of the ash also increases the risk of plugging of the conveyor line. The temperature of the ash entering the collecting vessel is preferably less than 300 °C, more preferably 100 - 200 °C. The pressure difference between the supply vessel and the collecting vessel is preferably 0.1 - 1.0 bar or less than 0.3 bar for each 10 m of the conveyor line.

The conveyor systems according to the above-described first and second embodiments of the present invention can be used e.g. for conveying fly ash separated by a flue gas filter unit of a pressurized fluidized bed reactor used for combustion or gasification of material.

According to a third preferred embodiment of the present invention the collecting vessel has a tubular form and it is arranged in a vertical position so that ash enters the collecting vessel through its upper part. Typically, the proportion of the height and the diameter of the collecting vessel is at least 5, more preferably at least 10, but it can preferably be even over 30. Thus the first gas discharge pipe provided with a filter is preferably disposed in the lower part of the vessel and the ash discharge system in the bottom of the vessel. There are possibly a plurality of gas discharge pipes at various levels of the vessel. The filter attached to the discharge pipes can preferably be arranged inside the tubular collecting vessel in contact with the material to be conveyed.

When using the ash discharge system according to the third preferred embodiment, the ash disposal from the collecting

vessel is preferably controlled by an ash column having an approximately constant height in the tubular collecting vessel. As the carrier gas passes through the ash column, its pressure falls without any separate means so that ash can be removed from the lower part of the collecting vessel, directly to an ash container, e.g. at atmospheric pressure. This kind of a conveyance system is particularly suitable for removing coarse bottom ash, e.g. from the furnace of a fluidized bed reactor used for combustion or gasification of material.

10

The collecting vessel according to the above-described third embodiment can also be dimensioned so that it has a self-adjusting overfill protector. Thus the diameter and the height of the vessel have to be such that the airflow through the ash column slows down essentially before the ash column in the vessel is too high, whereby the ash conveyance to the collecting vessel is reduced or even stopped completely.

In all above-described embodiments the conveyor line comprises parts that can be oriented with any desired position, i.e. vertical, horizontal or oblique. If necessary, the flow of the particulate material in the conveyor line, especially where the line is bent, can be assisted by introducing small quantities of carrier gas, e.g. air, into the line continuously or intermittently.

The invention is characterized in that there are no valves for controlling the conveying speed of the ash in the ash conveyor line. There can be shut-off valves in the line intended to be used when a part of the system needs to be separated from the others, e.g. for maintenance.

In the following the invention will be described more closely with reference to the accompanying drawings, in which

Fig. 1 schematically illustrates an ash conveying system according to a first preferred embodiment of the present invention;

5

Fig. 2 schematically illustrates the outlet end of the ash conveying system according to a second preferred embodiment of the present invention;

10 Fig. 3 schematically illustrates the outlet end of the ash conveying system according to a third preferred embodiment of the present invention;

Fig. 1 illustrates an ash conveying system according to a first preferred embodiment of the present invention, the supply vessel 10, ash conveyor line 20 and receiving vessel 40 of which can be similar to those even in other preferred embodiments. The various embodiments differ from each other mainly in how the carrier gas discharge from the collecting vessel 30 and the pressure reduction of the collected material are arranged.

The invention is characterized in that particulate material containing reaction products of a reactor is conveyed pneumatically from a supply vessel 10 at a pressure of at least 2 bar, typically at 6 - 20 bar, to a receiving vessel 40, e.g. at atmospheric pressure, using the gas exiting the reactor as a carrier gas. When applying the invention the volume of the supply vessel is typically larger than the volume of the conveyor line and it can be assumed that the pressure of the supply vessel is constant.

The supply vessel 10 can consist e.g. of a bottom part of a filter for fly ash from a high pressure fluidized bed reactor

or it can be a part of the removal system for bottom ash from a fluidized bed reactor. In the former case the ash 12 collected in the supply vessel is powdered, compressible fly ash, whereas in the latter case the ash could be coarse. The 5 quality of the ash to be conveyed has to be considered when choosing the embodiment and the method, by which the system according to the present invention is applied.

In the supply vessel the ash temperature is typically 400 - 10 1200 °C and for precooling the ash the vessel can be provided with heat exchange surfaces 14, e.g. heat exchange pipes, in which water or steam circulates.

The ash is conveyed in a tubular conveyor line 20, in which a 15 heat exchange surface could be arranged, e.g. a sleeve 22 covering the line at least partly and having means 24, 25 for the recirculation of heat exchange medium, e.g. water or steam. By the heat exchange surfaces 22 the ash temperature can be reduced, e.g. to 150 - 300 °C.

20 It is possible to arrange means 16 for the introduction of fluidizing gas, e.g. air, at the bottom of the supply vessel. These can prevent the clogging of the lower part of the collecting vessel deriving from the arching of ash. Further, 25 fluidizing air can be mixed in the carrier gas used in the conveyance, and reduce its dew point. Thus the clogging of the conveyor line due to moistening as the result of ash cooling can be prevented.

30 In Fig. 1 the conveyor line 20 starts below the supply vessel, turns upwards after the horizontal section and leads again horizontally above the collecting vessel 30. In practice, the conveyor line can consist of parts with any desired position. To avoid the clogging of the line it could

be occasionally or continuously necessary to add small quantities of carrier gas 28, e.g. air, to some points of the line, especially to the bent sections.

5 The ash conveyor line 20 ends in the collecting vessel 30, to which a discharge conduit 50 for carrier gas is attached. The conveyor line 20 is preferably formed of an extension part 32 extending slightly into the collecting vessel and directing the ash towards the bottom of the collecting vessel 30 thus  
10 reducing the probability of the ash being entrained with the gas to the discharge conduit 50. The collecting vessel 30 is also formed so as to reduce the speed of the carrier gas essentially when flowing from the extension part 32 of the conveyor line 20 to the collecting vessel. Thus the  
15 collecting vessel serves as a settling chamber for ash separating a substantial part of the ash conveyed by the carrier gas.

In the embodiment according to Fig. 1 the discharge conduit  
20 50 is provided with a filter 52 and a control valve 54 for controlling the flow rate of the discharged carrier gas 56. The discharge conduit leads preferably to the open air or to a space essentially at atmospheric pressure. If the pressure  
25 of the receiving vessel differs from the atmospheric pressure, it is preferable to draw the discharge conduit 50 to a space essentially at the same pressure as the receiving vessel.

As ash can be entrained with the carrier gas to the filter  
30 52, the filter is provided with means 60 for cleaning the filter by giving intermittent gas pulses to the clean side thereof.

In the embodiment according to Fig. 1 the collecting vessel 30 is arranged immediately above the receiving vessel 40. The collecting vessel 30 is separated from the receiving vessel 40 by a gas tight valve 34. There is also a gas tight valve 5 36 between the collecting vessel 30 and the conveyor line 20.

The present invention is characterized in that the gas discharge speed is adjusted by a control valve 54 so as to convey ash in the line 20 as a dense suspension the flow rate 10 of the carrier gas being less than 5 m/s. Thus the erosion and consumption of carrier gas caused by the conveyance are relatively insignificant. Valve 34 is shut and valve 36 is open during the conveyance. It is to be noted that valve 36 is not used for controlling the conveying speed of the ash or 15 for stopping thereof.

In the technical solution according to Fig. 1 a valve 18 is also arranged between the supply vessel 10 and the conveyor line 20. The system may include such a valve and possibly 20 even other valves not marked in the figure, as they do not have any significance from the viewpoint of the present invention. Valve 18 could be needed e.g. when maintaining the system, but in normal operation the valve is open.

25 When the level transmitter 38 attached to the collecting vessel 30 indicates that the collecting vessel is about to get filled, the ash conveyance is stopped. The carrier gas flow is stopped by shutting valve 54. When the ash conveyance is stopped, valve 36 is shut. After this, valve 54 is 30 reopened and the pressure of the collecting vessel is allowed to fall so that it is essentially the same as the pressure of the receiving vessel and the ash can fall down into the receiving vessel by opening the valve 34.

To restart the ash conveyance, valve 34 is shut, valve 36 is opened and the ash flow rate is adjusted by valve 54 to a desired value. To protect valve 36, it could be necessary to raise the pressure of the collecting vessel essentially to 5 the same level as that of the supply vessel 10. This can preferably be performed by using a system 60 producing cleaning pulses for the filter 52 of the discharge conduit 50. Simultaneously, the filter is also cleaned from ash possibly collected on its surface at the preceding filling 10 stage of the collecting vessel. The receiving vessel can be provided with heat exchange surfaces 44 for the final cooling of the ash as well as with an opening for ash discharge 46 in the bottom of the vessel.

15 The ash conveyance system according to the present invention is preferably used intermittently also between the discharges of the collecting vessel 30 so that the temperature  $T_1$  of the ash entering the collecting vessel 30 at the end of the conveyor line 20 and the pressure difference  $\Delta p$  between the 20 supply vessel and the collecting vessel are monitored. When  $T_1$  or  $\Delta p$  is not within the predetermined limits, the discharge of carrier gas and the ash conveyance are stopped by valve 54. Sometimes it could be sufficient to perform the ash conveyance in a predetermined way intermittently. The ash 25 conveyance can also be stopped when it is detected that the volume of ash in the supply vessel falls below a predetermined level.

30 Fig. 2 schematically illustrates the outlet end of the ash conveying system according to a second preferred embodiment of the present invention. There the collecting vessel 130, receiving vessel 140, valves 136 and 134 and the parts missing in the figure are similar to those in the embodiment

according to Fig. 1. The operational principle of this embodiment is also similar to that of the embodiment according to Fig. 1.

5 The second preferred embodiment according to Fig. 2 differs from the first preferred embodiment according to Fig. 1 in that the discharge conduit for carrier gas is in communication with the receiving vessel 140. Thus also the ash entrained with the carrier gas is led to the receiving  
10 vessel 140. Naturally, when using the second preferred embodiment according to Fig. 2, the receiving vessel has to be provided with a discharge conduit 162 for gas, e.g. to the open air, and a filter 162 preventing the ash from being entrained out with the gas.

15 In the embodiment according to Fig. 2 the discharge conduit is divided into three parallel conduits 150, 150' and 150'' joining to one conduit 160 before reaching the receiving vessel 140. As the ash entrained with the carrier gas could  
20 deteriorate the operational condition of the control valve, the control valve 54 of Fig. 1 has been replaced by steadier shut-off valves 154, 154', 154'' and critical openings 158, 158', 158'', like or unlike each other, restricting the gas flow. Naturally the number of parallel conduits can also be  
25 different from three.

In the embodiment according to Fig. 2 the ash conveying speed can be controlled by opening a necessary number of the shut-off valves 154, 154', 154''. If ash is conveyed periodically,  
30 the extent of the conveyance can also be regulated by changing the duration of the periods, whereby it is not necessary to have more than one discharge conduit, shut-off valve and critical opening.

Fig. 3 schematically illustrates the outlet end of the ash conveying system according to a third preferred embodiment of the present invention. In this embodiment the collecting vessel 230 at the end of the conveyor line is narrow and 5 high, even though its diameter is larger than that of the conveyor line. The proportion of the height of the collecting vessel to its diameter is preferably at least 5, most preferably at least 10.

10 When conveying ash, an ash column is maintained in the collecting vessel extending preferably at least to the center part of the vessel. In the embodiment according to the figure the ash flow is regulated by a discharge conduit 250 for carrier gas attached to the center part of the collecting 15 vessel, in which conduit the volume of carrier gas 256 can be regulated by a valve 254. At the end of the discharge conduit closest to the collecting vessel is arranged a filter 252 preventing the ash from entering the discharge conduit 250. When the filter is disposed according to the figure inside 20 the ash column flowing downwards, the moving ash simultaneously cleans the outer surface of the filter and prevents the filter from being clogged up.

Another advantage gained by arranging the first end of the 25 discharge conduit in the area of the ash column is that the portion of the ash column above the joining point of the discharge conduit also acts as a restrictor for the carrier gas flow. Thus the ash conveyance is partly self-adjusting as the high ash column slows down the gas flow and reduces or 30 even stops the ash conveyance, when the collecting vessel is about to get filled.

The discharge conduit 250 can also be arranged in the upper part of the collecting vessel, whereby it functions in the

same way as the discharge conduit according to the first preferred embodiment in Fig. 1. It is also possible to connect the discharge conduit 250 to the lower part of the collecting vessel 230, whereby the flow regulating effect of 5 the ash column is at its highest.

Fig. 3 also shows another discharge conduit 260 for gas provided with a filter 262 and a control valve 264. The purpose of the discharge conduit 260 is to let the carrier 10 gas 266 discharged from the lower part of the collecting vessel enter the open air without any particular obstruction, i.e. during the ash conveyance valve 264 does not essentially limit the gas flow. Thus the lower part of the collecting vessel 230 reaches the atmospheric pressure and the ash 272 15 can be easily removed from the lower part of the collecting vessel to the receiving vessel, e.g. by using a lockhopper 270. The discharge apparatus for ash at the bottom of the collecting vessel can also be another, e.g. a conveyor screw or an L-valve. Pressure adjusting in the collecting vessel 20 can also be practiced in many steps, whereby more than the mentioned two discharge conduits for gas are disposed in the collecting vessel.

Fig. 3 also shows a level transmitter 238 provided in the 25 upper part of the collecting vessel, and an apparatus 258 for feeding high pressure cleaning pulses to the filters 252 and 262. The collecting vessel can also be used so that the upper surface of the ash column is continuously maintained on a desired predetermined level by using a lockhopper 270. 30 Another possibility is to use a lockhopper intermittently, whereby the ash level remains within certain predetermined limits.

When starting the ash treatment system according to Fig. 3, e.g. sand can be fed to the collecting vessel through a separate conduit not shown in Fig. 3, whereby a sand column restricts the gas flow at the starting stage.

5

The invention has just been described in connection with embodiments that are presently considered as the most preferable, but it must, however, be understood that the invention is not limited to these embodiments only, but it also covers a number of other arrangements within the scope of invention determined by the patent claims below. E.g. a plurality of ash conveyor lines can lead into the same collecting vessel.

1000122604 05552005

Claims

1. Method of conveying particulate material containing reaction products of a high pressure reactor, from a supply vessel at a pressure of at least 2 bar to a receiving vessel at a considerably lower pressure, by using an apparatus comprising a conveyor line attached to the supply vessel and a collecting vessel between the conveyor line and the receiving vessel, where said collecting vessel comprises a discharge conduit for carrier gas and means to control the discharge rate of the carrier gas, said method comprising the step of
  - (a) conveying particulate material from the supply vessel to the collecting vessel pneumatically by using the gas exiting the reactor as a carrier gas, and controlling the discharge rate of the carrier gas to control the flow rate of the particulate material in the conveyor line,  
characterized in that in step (a) the pressure in the collecting vessel is controlled by using said means to control the discharge rate of the carrier gas so that material is conveyed from the supply vessel to the collecting vessel essentially at the same pressure as is prevailing in the supply vessel,  
and that the method comprises the further steps of
    - (b) reducing pressure of the material collected in the collecting vessel, and
    - (c) conveying material from the collecting vessel directly to the receiving vessel essentially at the same pressure as is prevailing in the receiving vessel.
- 30 2. Method of conveying particulate material according to claim 1, characterized in that step (a) is practiced by conveying particulate material as a dense suspension the flow rate of the carrier gas in the conveyor line being less than 5 m/s and the pressure drop 0.1 - 1.0 bar.

3. Method of conveying particulate material according to claim 1, characterized in that the temperature of the particulate material in the supply vessel is 400 - 1200 °C and the conveyor line is provided with heat exchange surfaces, by which the temperature of the particulate material in step (a) is reduced to less than 300 °C.

4. Method of conveying particulate material according to claim 10 3, characterized in that the particulate material in the supply vessel is fluidized by air that is mixed in the carrier gas decreasing the dew point thereof.

5. Method of conveying particulate material according to claim 15 1, characterized in that a filter is arranged in the discharge conduit for carrier gas, the means to control the flow rate of the gas includes a control valve downstream from the filter, and in step (a) the carrier gas is discharged from the collecting vessel to a space at the pressure which is 20 essentially the same as is prevailing in the receiving vessel.

6. Method of conveying particulate material according to claim 1, characterized in that the carrier gas is discharged from the collecting vessel to the receiving vessel in step (a).

25 7. Method of conveying particulate material according to claim 6, characterized in that more than one parallel lines for the discharge of carrier gas are provided between the collecting vessel and the receiving vessel, which lines are provided with 30 a constantly open flow restricting element and a shut-off valve, and the control of the discharge velocity is performed by opening and shutting the shut-off valves.

8. Method of conveying particulate material according to claim 7, characterized in that the flow restricting elements are easily changeable.

5 9. Method of conveying particulate material according to claim 5, characterized in that the collecting vessel has an elongated form and it is arranged in a vertical position, and a column of particulate material is maintained in the collecting vessel, and the discharge conduit for carrier gas 10 is attached to the collecting vessel at the bottom section of the particulate material column.

10. Method of conveying particulate material according to claim 9, characterized in that more than one discharge conduit 15 for carrier gas are provided and these are attached to the collecting vessel at various levels of the particulate material column.

11. Method of conveying particulate material according to claim 9, characterized in that the pressure in the bottom 20 section of the particulate material column is approximately the same as is prevailing in the receiving vessel and step (c) is practiced intermittently or continuously from the bottom section of the collecting vessel.

25 12. Method of conveying particulate material according to claim 1, characterized in that a gas tight inlet valve is disposed in the conveyor line before the collecting vessel and a gas tight discharge valve is disposed between the collecting 30 vessel and the receiving vessel, and steps (a) - (c) are practiced in alteration steps (b) and (c) comprising the sub-steps of:

(b1) stopping the discharge of carrier gas from the collecting vessel by using the means to control the carrier gas flow, whereby the conveyance of particulate material is stopped;

(b2) closing the shut-off valve before the collecting vessel;

5 (b3) allowing the discharge of carrier gas from the collecting vessel until the pressure in the collecting vessel has dropped approximately to the same level as the pressure of the receiving vessel;

(c1) opening the discharge valve and conveying the particulate material from the collecting vessel to the receiving vessel;

10 and

(c2) closing the discharge valve, opening the inlet valve and returning to step (a).

15 13. Method of conveying particulate material according to claim 1, characterized in that the collecting vessel is disposed above the receiving vessel and in step (c) the particulate material is allowed to fall down to the receiving vessel.

20 14. Method of conveying particulate material according to claim 1, characterized in that in step (a) the flow rate of the carrier gas is periodically changed by stopping the conveyance for a predetermined time at regular intervals or when the pressure in the collecting vessel or the temperature of the material entering the collecting vessel is not within predetermined limits.

30 15. Apparatus for pneumatic conveying of particulate material containing reaction products of a high pressure reactor from a supply vessel at a pressure of at least 2 bar to a receiving vessel at a considerably lower pressure, said apparatus comprising a conveyor line attached to the supply vessel and a collecting vessel between the conveyor line and the receiving

vessel, where said collecting vessel comprises a discharge conduit for carrier gas and means to control the discharge velocity of the carrier gas from the collecting vessel, characterized in that the collecting vessel comprises means to control the pressure of the material collected in the collecting vessel, and said apparatus comprises means for conveying the material directly from the collecting vessel to the receiving vessel essentially at the same pressure as is prevailing in the receiving vessel.

10

16. Apparatus for conveying particulate material according to claim 15, characterized in that heat exchange surfaces are disposed in the conveyor line.

15

17. Apparatus for conveying particulate material according to claim 16, characterized in that elements for fluidizing the particulate material are disposed in the supply vessel in such a way that air used for the fluidization is mixed in the carrier gas thus decreasing the dew point of the carrier gas.

20

18. Apparatus for conveying particulate material according to claim 15, characterized in that a filter is disposed in the discharge conduit for carrier gas, the means to control the flow rate of the carrier gas including a control valve is arranged downstream from the filter, and the discharge conduit for carrier gas is in flow communication with the open air.

25

19. Apparatus for conveying particulate material according to claim 15, characterized in that the discharge conduit for carrier gas is in flow communication with the receiving vessel.

30

20. Apparatus for conveying particulate material according to claim 19, characterized in that more than one parallel lines

for the discharge of carrier gas are provided between the collecting vessel and the receiving vessel, which lines are provided with a constantly open flow restricting element and a shut-off valve.

5

21. Apparatus for conveying particulate material according to claim 20, characterized in that the flow restricting elements are easily changeable.

10

22. Apparatus for conveying particulate material according to claim 15, characterized in that the collecting vessel has an elongated form and it is disposed in a vertical position, and the discharge conduit for carrier gas is attached to bottom section of the collecting vessel.

15

23. Apparatus for conveying particulate material according to claim 22, characterized in that more than one discharge conduit for carrier gas are provided and these are attached to the collecting vessel at various levels.

20

24. Apparatus for conveying particulate material according to claim 15, characterized in that a gas tight valve is disposed in the conveyor line before the collecting vessel and between the collecting vessel and the receiving vessel.

25

25. Apparatus for conveying particulate material according to claim 15, characterized in that the collecting vessel is disposed above the receiving vessel and a valve is arranged between the vessels, through which valve the particulate material may fall down to the receiving vessel.

(54) Title: METHOD AND APPARATUS FOR TREATING HIGH PRESSURE PARTICULATE MATERIAL

WO 01/00313 A1

(57) Abstract: A method and an apparatus for conveying particulate material of a reactor pneumatically from a high pressure delivery vessel (10) to a receiving vessel (40) at a lower pressure using gas discharging from the reactor as a carrier gas, by using an apparatus comprising a conveyor line (20) and a collecting vessel (30), which collecting vessel comprises means (50) to discharge carrier gas and means (54) to control the flow rate of the carrier gas, in which the pressure in the collecting vessel is controlled in such a way that the material has almost the same pressure as the delivery vessel when conveyed to the collecting vessel, from which it is transferred to the receiving vessel essentially at the same pressure as the receiving vessel.

**COMBINED DECLARATION AND POWER OF ATTORNEY  
FOR PATENT APPLICATION**

As the below named inventor, we hereby declare that.

Our residences, post office addresses and citizenships are as stated below next to our names;

We believe we are the original inventors of the subject matter which is claimed and for which a patent is sought on the invention entitled METHOD AND APPARATUS FOR TREATING HIGH PRESSURE PARTICULATE MATERIAL, the specification of which was filed as United States Application no. 10/018,804, based on PCT International Application No. PCT/FI00/00546, filed on June 19, 2000 and was amended on \_\_\_\_\_ (if applicable)

We hereby state that we have reviewed and understand the contents of the above-identified specification, including the claims, as amended by any amendment referred to above

We acknowledge the duty to disclose information which is material to patentability as defined in 37 CFR §1.56

We hereby claim foreign priority benefits under 35 U.S.C. § 119(a)-(d) or §365(6), of any foreign application(s) for patent or inventor's certificate, or § 365(a) of any PCT international application which designates at least one country other than the United States, listed below and have also identified below any foreign application for patent or inventor's certificate, or PCT international application having a filing date before that of the application on which priority is claimed:

| <u>Country</u> | <u>Application No.</u> | <u>Filed (Day/Mo /Yr.)</u> | <u>(Yes/No)</u><br><u>Priority Claimed</u> |
|----------------|------------------------|----------------------------|--|
| Finland        | 991459                 | 28/6/1999                  | Yes  |

We hereby claim the benefit under 35 U.S.C. § 120 of any United States application(s), or § 365(c) of any PCT international application designating the United States, listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States or PCT international application in the manner provided by the first paragraph of 35 U.S.C. § 112, we acknowledge the duty to disclose information which is material to patentability as defined in 37 CFR § 1.56 which became available between the filing date of the prior application and the national or PCT international filing date of this application.

| <u>Application No.</u> | <u>Filed (Day/Mo./Yr.)</u> | <u>Status</u><br><u>(Patented, Pending, Abandoned)</u> |
